MR. HARRY CHESTER.—The Sub-committee on Meat has met repeatedly. We have had before us various suggestions, descriptions, and samples of methods of preserving meat. We have given particular attention to those which profess to aim at the introduction of additional supplies of animal food from beyond sea. A sample of beef salted at Buenos Ayres, on Mr. Morgan's plan, by injection, was free from all objection on the score of putridity, but was very salt and rather tasteless. The meat at present to be obtained in South America appears to be very inferior to English meat. A perusal of Latham's “States of the Rio de La Plata,” published by Longmans, will explain the causes of the inferiority of their meat. The governments of these states are anxious to extend the manufacture and sale of preserved meat; but their energies should, in the first instance, be applied to the improvement of their agriculture, to the renovation of their impoverished pastures, to the improvement of the breeds of cattle and sheep, to their better management, and to more skilful butchering. The meat must be improved before it can come into successful competition with the meat of the United Kingdom or of Australia. These remarks do not apply to the manufacture *Extractum carnis* (Liebig) in South America, for there is no reason to suppose that the *Extractum carnis* sent from there to this country is inferior in quality to that manufactured elsewhere. The Committee have had before them various samples of *Extractum carnis* manufactured in South America, in Australia, and in this country. They are all stated to be made from the formula given to the world by Baron Liebig, and the Committee have no reason to suppose that one is much better than another. The Committee have carefully considered the various opinions which have been given respecting this kind of food. It is dried beef-tes, and the present scientific view appears to be that it is not an article on which alone life could be sustained, but is valuable under certain limited conditions. In the first place, it is very portable; and, in the second place, it will keep good for an almost unlimited period, and in any temperature. For the limited purposes which it subserves a very small quantity goes a great way. It contains none of the fibrin or albumen of meat, but then those necessary substances are intentionally eliminated by Liebig, as not capable of being preserved for any length of time, and it is stated that they may be conveniently substituted by vegetable fibrin and albumen. The addition of eggs, or of some ripened grain seeds, to *Extractum carnis* is said to supply the deficient ingredients, and *Extractum*

has been recommended as a convenient and economical substitute for the beefy element in gravy soup and gravies, which are commonly made from stock meat. It should be borne in mind that of every hundred pounds' weight of beef about 75 pounds' weight is nothing but water, and when from the remainder the weight of the bone has been deducted, the residuum which is capable of being assimilated is very small, and that part of the residuum which is neither albumen nor fibrin, though important in its effects, may be concentrated in a small gallipot. At any rate, *pro tanto*, the increasing sale of *Extractum carnis*, which may be obtained at almost any chemist's or Italian warehouseman's, as it comes from distant countries, is an addition to our supplies of meat. I may add that another preparation, Dr. Hassall's Flour of Meat, which appears also to have a considerable sale, is stated by that gentleman to contain albumen, fibrin, gelatine, and fat, which are wanting in the *Extractum carnis*. The Committee has every reason to believe that this also is a preparation of considerable value. Returning for a moment to Mr. Morgan's process of salting meat, I may say that the Committee has obtained from the Admiralty a return, giving the opinions expressed by the officers and crews of various vessels in the Royal Navy, who had tried the article. The letter from the Admiralty remarked that the unfavourable opinions preponderated; but weighing the opinions as well as counting them, and bearing in mind the prejudice likely to be entertained against a new article of diet, the Committee were by no means led to conclude that Mr. Morgan's process had been shown to be a failure. The Committee had before them a specimen of beef preserved in paraffine by Professor Redwood's process; but as this had had but scant justice done to it by the cook, they could not pronounce an opinion upon it. Messrs. McCall, of Houndsditch, exhibited a specimen of South American beef, which was preserved in November, 1865, by the process patented by Messrs. McCall and Sloper. This sample was quite free from putridity; but the Committee require further information before they can pronounce on its merits. They have also had before them several samples of preserved beef imported from Australia by Messrs. McCall. This is "Tindal's Australian boiled beef." Messrs. McCall have received the first consignment of 60,000 lbs. weight; and arrangements are made for similar arrivals monthly. It appears to be prime beef, not salted, free from bone, and cooked ready for table, and is sold at 7d. per pound, in six-pound tins. This is about equal in price to uncooked meat, with bone, at 6d. or 5½d. per pound. It is therefore cheap as well as good; and, as the supply can be enlarged to almost any extent, it is an important addition to our markets, and may even affect their prices. The process by which the meat is preserved is an old one—hermetically sealing in tins. The Committee are not at present in a position to report fully respecting an invention which promises valuable results in the hands of Professor Gamgee. The Committee, and several scientific gentlemen, who attended by his invitation, were present on two occasions when bullocks and sheep were killed by a painless process, and their flesh was subjected to a preserving process invented by the Professor. Specimens of the meat thus treated have been sent to the tropical departments at Kew and the Crystal Palace; and it is proposed to send other specimens to Australia, and to South America, to ascertain whether it will stand the test of the outward and homeward voyages, with their extremes of temperature.

The Sub-Committee on milk has also had repeated meetings. On this head the most important questions affecting the supply of milk for the metropolis, and other large towns, appeared to be mainly questions of transit by railway. The Committee has obtained returns giving various particulars from the milk-carrying railway companies; but as those returns are at present incomplete, I cannot now state their effect. Mr. C.

Alexander Wood, a director and vice-chairman of the Great Western Railway Company, has kindly attended the Sub-Committee, and had brought with him Mr. Nicholson, the company's superintendent of parcels at Paddington; and the information given by those gentlemen will shortly be published.

Lord de L'Isle, a member of the Committee, has procured for its information an account of the system of cotters' cowkeeping which prevails in the North of Scotland, and is there valued as affording not only pecuniary means of support to the cotter, but opportunities for the purchase of small quantities of milk for the poor, and also a useful training in cleanly, industrious habits for the wives and daughters of the cotter, who are thus enabled to learn to make butter and manage dairy accomplishments which are rarely found in the west of the south. This it is also intended to publish.

Baroness Leinsner-Ebersberg, who stated that she had patented in this country, under authority of Baron Liebig, his invention of Food for Infants, viz. she called Liebig's "Concentrated Milk for Infants," forwarded to the sub-committee a sample, manufactured by Mr. Mullen, of Titchbourne-street, which was used by the committee and found palatable. It was stated in her communication that Baron Liebig declared this preparation to be the chemical equivalent of mother's milk, and therefore the best possible food for such infants as are necessarily brought up by hand. The term, "concentrated milk," appears to be a misnomer. It is in fact cow's milk, to which a small quantity of potash and finely-ground malt has been added. The Baroness said that she was forming a chemical society for the gratuitous distribution of this milk to the poor. The Committee have had before them a lactometer which is used by the police in Paris to test the purity of the milk sold there. It clearly shows whether the milk is diluted with water, and to what extent. A similar lactometer, or milk test, purchased for one shilling in London, was also tried and found to act with correctness.

The SECRETARY then read a letter, addressed to Mr. Harry Chester, by Professor John Gamgee, on the subject of the preventible diseases among the birds and flocks of this country. It was resolved that the letter be published in the Society's Journal, and that a copy of it be sent to the Home Office and to the Board of Trade, with the expression of the Committee's hope that the subject, which was of very great national importance, might receive attention from Her Majesty's Government.

A Sub-Committee, on "Cooking and Cooking Apparatus," was appointed. The Committee then adjourned.

CANTOR LECTURE.

"ON MUSIC AND MUSICAL INSTRUMENTS."
HULLAH, Esq.

LECTURE III.—MONDAY, MARCH 18.

MUSICAL EXPRESSION.

In commencing his third lecture, Mr. Hullah was especially necessary, in the present instance, to exactly the thing he was about to discuss, because the word "expression," in connection with music especially, was often used to represent that of which it was the vehicle, sentiment. As applied to musical performance there might be some excuse for this confusion of ideas, but as applied to musical composition there was no excuse. Musical composition is expression; and it is the poser who expresses, while the performer presents the composer's expression. But before admitting the identity of musical expression with musical composition, we must be quite sure to what process the term composition can be applied. The conditions under which it is practised are p

Unlike any other artist, the musician requires long and special training before he learns how to realise the effect, in performance, of what he puts on paper. The musician must, so to speak, be able to hear with his eyes. An anecdote was given, related of himself by Rousseau, who, altogether ignorant of the effect of musical successions and combinations, had put on paper a Symphony the performance of which had been attended with the most disastrous results. Ignorance so absolute as Rousseau's was rare among would-be composers in modern times; but not so in ancient, even among trained musicians, and for a very simple reason; that composers, even down to the middle of the 16th century, had not ready access to those keyed instruments which present such a ready mode of testing musical effects. History shows that music has taken longer to attain excellence than any other of the fine arts. To a great extent this is attributable to the latter being revived arts; whereas music, in our acceptance of the term, is a new art. But its comparatively slow progress is due also to the difficulty which the earliest harmonists had in appreciating the effect of what they wrote. A fourteenth-century M.S., recently discovered at Montpellier, has been found to contain no less than three hundred and forty pieces of vocal music, in two, three, and four parts, by composers of the twelfth and thirteenth centuries. The melodies of many of these are very pleasing, but the harmonies are insupportable to a modern ear. In proof of this, Mr. Hullah played one of them, first without accompaniment and then with its contemporary harmony. Why was the harmony so inferior to the melody, both being of the same age and country?—Simply because the effect of melody could be ascertained in the very act of making it, while that of harmony, in these early times, had to be guessed at, or ascertained by processes too troublesome to be often brought into requisition. Moreover, musicians who wrote even as late as the end of the sixteenth century had other difficulties to contend with. Their *tonality* was different from ours and essentially empirical. Not that the old masters were altogether ignorant of modern tonality, but that they were very timid and slow in adopting it. The many changes in musical practice which were finally universally accepted only towards the end of the seventeenth century, turn, for the most part, on a more philosophical tonality. Everything that essentially distinguishes modern music from ancient is due to this. To the general acceptance of modern tonality we owe the distinguishing characteristics of modern music—*expression*,—that quality, in any given musical passage which, by whatever means, is able to put those who listen to it in a condition of mind accordant with, and like that of its author, at the moment of its conception. Till recent times, few essays in musical expression had been made save in vocal music, and these were much aided, as they had been dictated, by the words with which they were connected. Expression, by means of music pure and unaided, is altogether a new art. The attention bestowed on musical expression during the 17th century is mainly the efforts of a body of amateurs living in Florence, who sought to remedy the shortcoming of the music of that time by a revival of that of the Greeks. They succeeded in abolishing polyphonic music nor in restoring the music of the ancients, but they compelled composers to give more attention, as well to the sentiment of the words they set, as to their ornamentation and quality. Indeed, for a considerable time music was rather open to the reproach of *over-ornamentation* than the reverse, and a style of composition general in which notes waited on words with a simplicity always servile and often ridiculous. The efforts of the 17th and 18th centuries. This kind of ornamentation was advocated by many of the theorists of the time, among others by Christopher Symphon, in his *pendium or Introduction to Practical Music.*

Contemporary composers certainly acted in the spirit of Symphon's instructions. Purcell has gone the length of imitating a drunkard, in musical notes, even to his stagger and hiccough; and his predecessor, Matthew Lock, has set the responses to the Commandments in ten different ways, each setting being, as he considered, characteristic of the Commandment which it followed. But mistakes in musical expression, or rather misapprehensions of the powers and uses of music, have been made by greater and more recent masters; for it is surely a mistake, and a misapprehension of the powers and uses of music, to deal with it as an imitative art. In the hands of a great master music is a suggestive art. When a musical passage is fairly performed, the sentiment of the composer will be communicated to the auditor, provided that it be a sentiment, not a circumstance, a material object, or a mere conceit. Their several musical expressions can be found for passions and feelings, but not for events, accidents, natural phenomena, &c., the representation of which in music generally proved impossible, and where not impossible, ludicrous. Mr. Hullah illustrated this by extracts from a work, Haydn's "Creation," on which, as a whole, he passed a warm eulogium, and related an anecdote of the great composer's failure in representing a storm at sea by pure musical sounds. After an account of some attempts at musical imitation, dating as far back as the beginning of the sixteenth century, the majority of which were purely vocal, the lecturer spoke of the purely instrumental attempts which had distinguished the end of the last and the beginning of the present centuries, when it reached its apogee of absurdity. He described a number of pianoforte pieces, commemorative and descriptive of the great events, especially the battles of land and sea, of that epoch. Most of these were *opera obsecrorum virorum*; but some few were by musicians of considerable eminence,—among them, Steibelt and Dussek. A piece by the latter bore the title of "The Sufferings of the Queen of France: a musical composition expressing the feelings of the unfortunate Marie Antoinette, during her imprisonment, trial," &c. One only of this legion of descriptive pieces had escaped the well-deserved oblivion which had attended all the others, Kotzwara's "Battle of Prague," with which the present generation of pianists keep up at least a bowing acquaintance, and which was anything but unknown to the music-sellers. In conclusion, Mr. Hullah said that the only legitimate field for the exercise of musical imitation was comedy—he would almost say burlesque. The province of the musical art was, he repeated, suggestion, not representation; and every attempt at representation by means of musical sounds, whether of "moving accidents by flood or field," natural phenomena, or aught else, must, of necessity, fail—as was proved, if proof were wanting, by its always wanting commentary—notes explanatory of notes; and where such imitation was least imperfect it was, perhaps, most ridiculous. To define, even approximately, true musical expression would be a difficult task,—one, however, which all who studied music could at least partially perform for themselves. Innumerable examples of it were to be found in the best, and perhaps, on the whole, most familiar works of the great composers; those, especially, who have written since the beginning of the last century, who, unlike many of their immediate predecessors, had governed expression, not allowed expression to govern them, and had never forgotten that, without beauty of form, truth in art was incomplete.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 20th, 1867; The Rt. Hon. STEPHEN CAVE, M.P., Vice-President of the Board of Trade, in the Chair.

The following candidates were proposed for election as members of the Society:—

Folliott, William, 12, Idmiston-villas, Forest-gate, S.E.
 Lewis, R., 18, St. James's-street, S.W.
 McCall, J., C.E., 137, Houndsditch, N.E.

The following candidates were balloted for, and duly elected members of the Society :—

Beaumont, Somerset, 144, Piccadilly, W.
 Dunderdale, James, Tiverton-lodge, Cheetham-hill, Manchester.
 Hopkin, W. K., 5, New Cavendish-street, W.
 Hutchinson, Robert Hopwood, Tenter-house, Rochdale.
 Karslake, Sir John B., M.P. (Solicitor-General), 50, Pall-mall, S.W.
 Nield, Jonathan, Dunster-house, Rochdale.

The Paper read was—

SUCCESSFUL OYSTER CULTURE.

By HARRY LOBB, Esq.

The paper I shall have the honour of reading to you to-night is on the subject of "Successful Oyster Culture," and has been called forth by the dearth of oysters, and the consequent great increase in price of this favourite mollusc. The cause of this dearth is constantly being inquired for. Many reasons have been given, most of them erroneous; I will therefore endeavour to lay before you the true cause of the increase in the price of the oyster, and the way to reduce it to its normal figure, "fourpence a dozen, retail, for the best natives." You must excuse me if I do not refer to the ancient Britons or Romans, or any of the more remote oyster-culturists, as I shall hardly have time to consider more than the last ten years of the science.

The cause of the great price of oysters is their scarcity. The demand for oysters has increased with the population and the facilities for traffic;—the price has increased,—the dredgermen have increased in numbers, and, after having exhausted the home beds, they have done the same with the Scotch and Irish beds, until at length all the available oysters have been eaten up, and none left to re-stock the beds. This state of things is not peculiar to the British Isles; our neighbours found themselves in precisely the same condition about the same time. Singularly enough, the English, unlike their usual method of behaviour in case of difficulty, began to mourn over the loss, and to search for some cosmical cause for the disease ravaging their oyster beds. True there was a disease, bearing the fatal name Consumption! but this was not discovered at the time. The French, led by M. Coste, and under Imperial patronage, at once set about to remedy the evil. All my hearers are acquainted with the story of the mason of the Ile de Ré, M. Boeuf, who established the first artificial breeding bed; his success led to an immense industry, where some 2,000 proprietors of beds raised some hundreds of millions of oysters; but as I do not consider the Ile de Ré system adapted to our shores, I pass it over, merely recording the fact, as the first success, and the origin of all future attempts. Let me, however, chronicle a few statistics of the Rivedoux beds, premising that the labour bestowed is not hired, but simply that of the proprietors and their families, at such times as they can spare from their other avocations. The following is the result of the sale of oysters from the beds of Rivedoux, about a mile in length, by 150 yards in width:—From 1859 to 1860, £126; 1860 to 1861, £320; 1861 to 1862, £1,520; and from 1862 to 1863, upwards of £2,000.

M. Coste now took the matter up in a scientific spirit, and having been informed of the complete denudation of oysters of the basin of Arcachon, he turned his attention to this spot. The basin of Arcachon, situated near Bordeaux, is a land-locked indentation of the Bay of Biscay, a narrow channel, admitting the tide. It is a very large area, of almost pure sea-water, two small rivers, the Leyre and the Teeste, emptying themselves into it. There is one island, and at low-water very extensive

banks are exposed, but at low spring tides there are 2,000 acres laid bare, and between these, deep channels draw off the water from the banks. It was these 2,000 acres M. Coste considered best adapted for his experiments, for being exposed for two hours twice a day during low spring tides, it afforded this time for working the beds, and yet the oysters were covered at all other times. After a month's study, M. Coste made his report, in which he speaks of the basin of Arcachon as "a veritable mine of wealth, which, by judicious cultivation, might be made to yield from its 2,000 acres of bottom, uncovered only at low spring tides, an annual revenue of £600,000." There being no oysters left in the basin for breeding purposes, others had to be brought, and artificial means taken to attract the spawn when given off. M. Coste established two beds, but one, since established, having been more successful, I will give its history. The following is from a report I drew up for the directors of the South of England Oyster Company, on my return from Arcachon last July :—

The bed which has yielded the greatest results is that of Lahillon, created by M. Chaumel, commandant of the brig *Leger*, the government guard-ship in the basin. In the year 1860, M. Chaumel was directed by the Minister of Marine to carry out M. Coste's recommendations as to oyster culture, and to report at regular intervals upon the results effected.

Lahillon is a long strip of sea bottom, 2,700 metres long by 180 broad, and only uncovered for two hours twice a day at low spring tide; it is situated in the middle of a broad channel, bordering the north-east coast of the Ile des Oiseaux. A strong current runs over this bank; this bed lies in the centre of the channel, washing the beds established by M. Coste. M. Chaumel considered this a favourable spot for his attempt, and, consequently, 100 acres of this bottom were thoroughly dredged by the men of the *Leger*; not an oyster was found, on account of the ravages of the whelk, and not a trace of spat; the bottom, which was covered with mud and weeds, was entirely removed to about 18 inches in depth, and the natural sandy bottom of the basin, mixed with shells, was arrived at; this was well covered with all kinds of shells, of which there are immense quantities, principally cockles and oysters. In June, 7,500 tiles were placed, arranged in 270 piles, termed *ruches*, so that the water could circulate freely through them; these tiles are about three feet long by about five inches broad, and are curved, forming about the third of an arc of a circle; they are not glazed, but are more vitrified and less porous than our common English tile; they are rough, and admirably adapted for the purpose for which they are required. They are piled at intervals on each side of a central path, running along the centre of the bed, about 30 to each pile, and rise about two feet from the ground, forming an oblong mass, about the size and shape of an ordinary clothes box. These 100 acres are divided into compartments, first into two, by a long walk lengthways, then smaller paths two feet wide running at right angles to that, and separated from each other by a distance of six feet; four of these divisions form a bed, and each bears a number upon a pole some seven feet high. The usual custom of the oyster-breeders in Arcachon is to lay down the tiles in April and May, when the oysters begin to sickle, but M. Chaumel says that in this case they frequently get covered with weed and mud, whereas he is himself accustomed to lay down his tiles in June and July, when the young oysters are ready to attach themselves, and finding a clean surface favourable to them they readily fix themselves to the tiles.

Upon the bed Lahillon a *ponton* (large boat) is moored in which four men live; they watch the pace, and are constantly at work when the tide serves for their labour, besides these the sailors from the *pinnace* work at low spring tides for two hours twice a day. Upon the beds 400,000 full-grown oysters from the adjacent par-

id down, and 400,000 more sea oysters from the 36; these oysters, during the following months of July, August, September, October, and November, spawn, and the spat adhered to the tiles, shells, &c. a very salient spot. The oysters emit spawn at different times during the aforesaid months, according to their nature and their state of health. The July is the largest. My visit to the bed took place the 10th of July, and M. Chaumel pointed out upon the tiles, oysters about the size of the surface split pea, which he said were 20 days old, that is had been attached 20 days; he did not reckon on they had been free, which time is not at all exactly known.

The expense of making the Bed Lahillon was £1,140. The results of the experiment and the returns are as follows, not counting the present season, of which no result has yet been computed:—

Young oysters on tiles	1,255,248
Young oysters attached to parents ..	2,680,060
Young oysters on cultch fascines, &c.	1,246,014
Total	5,181,262
Returns from the sale of oysters	£8,000
Deducted expenses	1,140

Profit realised **£6,860**

Besides the above, there remain upon the bed some 10,000 not yet fit for market, and of which the value has not yet been computed.

As the oysters, great numbers are destroyed by the rain, by the cold, by hail, by the sun, and other causes; in fact, M. Chaumel informed me he considered that a quarter of his oysters from these causes; the most destructive of the vermin is the *bigorneau* dog-fish, or piercer; these creatures appear in vast numbers in the spring; they are hatched out from nests, each containing about 800 eggs, and each egg 40 individuals; they pierce the shell of the oyster with an instrument adapted for the purpose, and the crabs follow in their wake, and soon clean out the dead oyster; one of the duties of the guards is at low spring tides to collect the whelks upon the bed, and one man has been known to pick up 14,000 in the two hours of the low tide.

At the end of the breeding bed, the tiles are laid down, covered with the result of last year's spat; there are from 1 to 300 upon each tile, and they are as close as they can be crowded; attached by their hinges to the tile, with their shells opening outwards, these oysters are exposed to the sun, and are entirely uncovered for two hours each day, during low spring tides, without apparent harm. Upon the bottom of the beds, where the parent oysters are placed, each one is covered with a crop of young, some twelve months old, and they form such a mass upon the shell of the parent, that the old oyster in some instances can hardly be distinguished, and some specimens are the size of a child's head.

All these young oysters are separated from the tiles and from their parents at the end of September and during the following months, and are laid in beds of sand and mud to fatten; they are fit for market at the end of the following September, and during that winter, the largest, of course, being first chosen; so that the oysters from the basin of Arcachon are fit to be eaten when they are 27 months' old; this is at least a year earlier than an English-bred oyster is fit to eat.

A strong westerly gale at spring tide, so as to fill the basin, and then the wind falling, so as to cause a great scour, is considered very favourable for the attachment of the spat; in fact there is no doubt that the great secret for a successful spat is extreme cleanliness. The temperature of the water in the basin of Arcachon is extremely uniform, night and day it varies but little; the nights are mild, and the water in the Bay of Biscay being fed by the Gulf Stream, the temperature is constantly warm. M. Chaumel told me that the average

summer temperature is 15° centigrade, and winter 5°. It never freezes at Arcachon, but the hail is sometimes very injurious to the young oysters.

The success obtained by the French naturally excited the desire of those interested in oyster culture in England to effect a like result; from what cause it were invidious to say; this was not done until a fitting site was selected, namely, the Island of Hayling. Here, however, we have almost similar conditions to those found at Arcachon; and no small credit is due to Mr. Hart for the acumen shown by him in his choice of this site. I suppose, if the whole sea-board of England were searched for a site for the cultivation of oysters, none could be found more suitable for the purpose of a breeding bed than the indentation on the east side of Hayling. Here we find an area of about 150 acres, covered at high tide by pure sea-water; a short embankment across the narrow neck would enclose this, and on the water being kept out a short time, the bottom would harden, and would work up into embankments by shingling the surface, and providing proper collectors. A breeding bed, sufficient to produce annually 500,000,000 young oysters, could be prepared in a few months. Mr. Hart, however, profiting by the formation of the Hayling railway embankment, considering that this—enclosing a large area of mud lands—would be the more eligible position, selected the western shore for his works. But before proceeding further, I will say a few words descriptive of Hayling and its fishery.

Hayling island lies at the mouth of a large area of sea water, which runs in from the Solent by two narrow channels on either side of the island, resembling in many respects the basin of Arcachon. The bottom at Hayling is chalk and flint; at Arcachon, sand; otherwise, the mud, the water, the weed, the channels, the mud banks, the protected site, the freedom from storms, from rough seas, from fresh water, are remarkably similar in the two localities. There are 10,000 square acres available for oyster culture; of these only the channels, up to the time of the South of England Oyster Company commencing proceedings, were worked.

The following is a brief history of the Hayling Oyster Fishery:—"In the reign of Henry II. the Emsworth fishery was valued at eight shillings and eight pence per annum to the royal treasury, and the harbour was from a very early date celebrated for the quality of its oysters, which are larger than the Thames natives, but considerably smaller than the Channel oysters. The local fishermen have ever looked upon strangers dredging in the harbours with jealousy, and have done all in their power to prevent it, although they themselves are not as a rule so provident as the deep-sea fishermen, who save their earnings to purchase vessels of larger tonnage and improved build. The harbour fishermen are satisfied to go on in the old routine, and seldom very much improve their position. Formerly the dredgers returned to the sea the young oyster and spat, reserving only the marketable oysters, but after a time they carried away with them all they removed with the dredge, retaining the small oysters to deposit in their own layings. The local men now believed that they were ruined, as the natural beds in the channel were rapidly being rendered barren, and as the demand for oyster beds increased, the lords of manors granted portions of mudlands to persons who cleared them, converting them into layings, and, according to the statute, planted sticks upon their boundaries, so that strangers should not dredge on their private beds. In these beds not only native oysters but Channel oysters were placed for fattening, for sale in the London market. This new system, however, did not suit the Emsworth fishermen, who, enraged at seeing the success of the new system and the destruction of the natural beds, determined to seize the oysters and destroy the artificial beds. They therefore combined amongst themselves, and commenced by attacking the oyster

beds belonging to the Messrs. Russell, in Crastick Lake; this resulted in some fighting, and at the assizes the fishermen at length discovered that they were not allowed to rob other people with impunity. The large dredgers still continue to move all they can get, and, according to some authorities, the dredging so disturbs and scarifies the bottoms and sides of the channels that the multiplication of the oysters is much increased, the spat is moved and distributed, and every year the number obtained increases. The artificial oyster beds contribute to this result, as the spat travels down the channels with the ebb tide, and by this means the area covered by spat is increased; every year we find the number of boats employed in this trade increase. The trade was formerly confined to the winter months, but now it is carried almost through the year. Oysters are obtained from all quarters, and laid in the beds for fattening, and the demand being so large and regular the trade is very remunerative. The best interest of the locality is to encourage this industry, which brings capital and labour into the neighbourhood, and must be of the utmost advantage to all concerned."

This account of the fishery was written some years ago, and very faithfully records its condition at the time; but since then the demand for oysters has considerably increased, and the dredgers, acting upon the French proverb, "After me the deluge," have every year advanced in their depredations, removing oysters, ware, and spat—the former for market, the latter to lay in their own private beds. Formerly the dredging was continued during the whole open time, so that the bottom was kept clean for the spatting, but as the dredgers increased in numbers—coming as they did from Whitstable and the Essex rivers, besides the local men—the oysters were removed in less time, therefore the bottom got more foul every year; and one week, in September, 1865, was sufficient to clear away all that was worth taking by the foreign dredgermen; and they all state that there was no trace of spat on account of the foulness of the ground. Thus it may be considered that the old-established Emsworth fishery is destroyed, and unless it becomes worth the while of companies, or private individuals, to cultivate these unproductive bottoms, it will never become re-established by natural means.

The South of England Oyster Company was instituted October, 1865, for the purpose of utilising the portion of mudlands inclosed by the Hayling Railway on the west coast of the island; forty-eight acres are now prepared, but it was found impossible to have the beds ready for the spat of 1866, and only one acre in a pond of four acres was thoroughly shingled and culched, and eighty large hurdles fixed above the oysters laid down for breeding. On the 14th of June these oysters were observed to be what is termed "sick," and emitting the spawn; on the 15th of July the whole of the under-surface of the hurdles was so thickly covered with minute oysters, as to almost completely hide the bark. The acre of shingle and culch is also covered with young oysters. The dead reeds and roots of grass bordering the pond, pieces of wood floating on the waters—in fact, every available attachment is thickly covered. This proves how thoroughly adapted the waters and temperature of Hayling are for the breeding of oysters.

It is necessary to understand something of the natural history of the oyster, so as to assist by artificial means the attachment of the spat. The young oysters are emitted from the parent in large numbers, forming a small cloud; each one is separate and independent, and they are not contained in any mucus; each oyster is protected by its shells, which it has the power of closing; beyond the edge of its shell it protrudes what has been termed its swimming pad, a double row of very long cilia, with which it is enabled to swim about in any direction; its usual position is with its swimming pad directed upwards, the hinge of the shell downwards, and its chief

motion is upwards and downwards; upon any unexpected motion of the water, it withdraws its cilia, closes the shell, and sinks to the bottom. To the left of the swimming pad is an opening, fringed with cilia, leading to the intestinal tube. The young oysters are found attaching themselves together in rows of five or six, or more—the swimming pad of the second to the hinge of the first, and so on—still rapidly swimming. How long this peripatetic condition lasts I do not know; I have had them in a common phial fourteen days, during which time they showed no inclination to attach themselves.

When they do fix themselves, they do so very firmly by the whole surface of the flat shell, and they cannot be removed without destroying the shell. At Hayling they prefer the clean bark of hurdles, wood, shingle, pieces of slate, &c. At Arcahon they prefer tiles, the external shell of parent oysters, &c. They select dark objects in preference to those of a lighter colour, and always attach themselves to the sides removed from the light; although guided by some law, they appear to be most capricious in the positions selected for attachment.

To show how hardy the spawn of the oyster is, and through what vicissitudes it will pass without injury, I have brought up from Hayling a specimen on the tile. On the 14th of June the oysters in the pond were found to be sick, and emitting spawn; on the 16th of July the spat was discovered attached to the hurdle placed for its reception, therefore during those 31 days the young oysters were free, swimming about the pond, on the east side of the pond is an adit, some hundred yards long; a windmill pumps water from this adit to a large wooden tank, from which the water is constantly running through a series of slate troughs, and from these to two wooden reservoirs; the overflow then runs into the lobster ponds; in these lobster ponds two or three large broken chimney pots were placed, as cover for the lobsters. Upon the inside of one of these pots I broke away this specimen of spat, which, you see, is 1½ inches across the long diameter, by 1½ inches the shorter; comparing it with the spat on the hurdles, it will be seen to be at least four times the size of the average, the reason being that this one, being by itself, has had the advantage of the nutritious matter surrounding it, whereas those on the hurdles had to share with their neighbours.

This oyster, whilst in its free condition, and in its almost microscopical, travelled down the hundred yard adit, was pumped up by the windmill into the tank here tens of thousands of its fellows were satisfied with their journeying, and attached themselves to the side and bottom of the tank, this one went on, passed through a long leaden pipe, swam down the six slate trough leaving behind some hundreds to attach themselves to the slate, through the two wooden reservoirs, then down an underground drain-pipe, into the lobster pond; here, satisfied with its travels, it attached itself to the inside of the chimney-pot, and flourished, and is the largest specimen I could find.

The young spawn avoid the light; they always attach themselves, where practicable, to the under side of objects. For instance, the hurdles were only covered on the under surface; they swarm under stones to fix to. They are found in large numbers in the holes and cracks of banks. When there are proper materials for attachment they always prefer dark substances, such as slate, or black stones; the dark in preference to the white wood. I do not think there is an exception to this rule. Again, they like quiet water and warmth, but not the direct rays of the sun; cold rains and hail are very destructive to the young brood. An even temperature, averaging about 62° Fahrenheit, day and night, is that most conducive to the security of the spat.

And now let us glance somewhat cursorily at the attempts at legislation, for the purpose of arresting the wholesale destruction of the oyster beds. A commission was appointed for the purpose of studying this question, and, desir-

by the evidence given, most of it being mere guess work, the commissioners issued a report, which I believe to have been the cause of much injury to natural beds. Upon this report the late Government, recognising the necessity for legislation, introduced a Bill, intitled, "An act to facilitate the establishment and improvement and maintenance of oyster and mussel fisheries in Great Britain." The bill was the offspring of the Board of Trade, and was fathered by the then president, Mr. Milner Gibson. Before the third reading, the Conservatives came into office, and Mr. Stephen Cave, whom I am happy to see in the chair this evening, became its step-father. Under its provisions applications were invited by the board, but the act being very vague, and the board wanting information, the first batch of memorials were refused without inquiry. These, however, afforded them information, and they issued a set of regulations, which facilitated matters so far as to point out what they will grant and what they will not.

"1.—General Principles on which exclusive Rights of Fishery will be granted."

"The following comprise the several classes of grants or concessions which appear to the Board of Trade to fall within the scope and intention of the above-named Act, and for which they will be prepared to receive applications:—

"1. Appropriations of moderate areas of unproductive sea-bed or foreshore for the establishment of new fisheries or local depôts.

"2. Appropriations of small areas of already productive ground for oyster layings or depôts in the vicinity of public beds.

"3. Concessions of exclusive fishery rights to owners or occupiers of existing fisheries, but within such limits and conditions only as may make such concessions beneficial to the public.

"Claims for grants coming under any of the following heads cannot, with a due regard to the public advantage, be entertained:—

"1. Appropriations of large areas of already existing public beds or productive dredging ground.

"2. Appropriations of larger extents of ground than the claimants have the means of beneficially cultivating, whether under the plea of regulating and superintending the fishery, or for any other purpose.

"3. Grants of licensing or sub-letting powers.

"The only ground for appropriating or granting exclusive fishery rights over any portion of the seashore is the expectation that by these means the supply of oysters will be materially increased, and the public thereby benefited. Such expectation must consequently be shown to exist in all cases of grants under this Act, and especially in the case of a grant of already productive dredging ground."

The Board of Trade appear to reason thus: "If the ground is, or has been prolific, we will leave it to the dredgers to work; but, if any company or capitalist come forward, we will only grant them an unproductive sea bottom, which, should they succeed in making valuable, will be to the public advantage, and will interfere with no vested rights." This is true enough. But what man would be so simple as to invest money to work a sea bottom proved to be unadapted to the purpose? Nature has already pointed out all the situations adapted for oyster culture, by sowing seed everywhere, and, as the seed is in such immense quantities, and free to choose its site for attachment, what with the currents, winds, and other causes, every place adapted for the purpose has been already discovered by the unerring instinct of nature. Almost all the natural breeding beds have been exhausted by reckless dredging. Many of these are now useless, from the cessation of dredging and the consequent accumulation of sludge and vermin; and, even should spawners visit these beds again, there would be no clean catch to offer attachment for the spawners.

Reckless dredging must not be confounded with constant dredging. The former is the result of the selfish policy of taking everything that can be obtained from the natural beds—in fact, destroying them—and is what has been done now for many years, chiefly by the White-stable men, who seek out every natural bed, wherever it may be, and do not leave it till it is dredged bare. They also encourage others in the same policy, by purchasing everything of the nature of an oyster that may be brought to them. These men, in their corporate capacity, are also examples of the second form of dredging; for they work their beds all the year round, thus keeping them fresh and clean; they move their oysters, destroy vermin, remove weed, in fact, take the greatest care of their growing and fattening beds, consequently turning out a very fine oyster, fetching the highest price in the market, at present £6 the bushel, or 1s. 8d. a dozen retail.

The Board of Trade having taken upon itself the responsibility of legislation to facilitate the formation of private beds, to increase the supply, and, consequently, lower the price of oysters, the public are somewhat disappointed to find that, up to the present time, nothing has been done, and the price of oysters is steadily increasing. It is hoped that this season may not be allowed to pass without some orders under the Act being granted.

The facilities desired by companies and capitalists are something of this nature:—

1. Upon clear proof that hitherto productive areas of sea-bed or foreshore have been rendered unprolific, and that the local or other dredgers have ceased to work the ground; that exclusive rights of fishery be granted over such areas to fitting applicants.

2. That foreshores, beds of rivers, lakes in harbours, &c., adapted for fattening purposes, shall be granted to applicants upon payment of reasonable royalty to the crown, corporations, lords of manors, &c., who may be proved proprietors of such foreshores, river beds, &c.

Allow me, in conclusion, to recapitulate the principal points in my paper, as follows:—

The cause of the increase in the price of oysters is, their scarcity.

The cause of the scarcity of oysters is, many years of reckless dredging.

The result of the many years of reckless dredging is, the destruction of the natural oyster beds.

The remedy is, the establishment of private breeding beds and the renovation of the natural beds by judicious legislation.

DISCUSSION.

Mr. CHOLMONDELEY PENNELL would be glad to have a little more information with regard to the success already achieved at the oyster grounds at Hayling, and as to the future results which were anticipated from them in a commercial point of view. He understood that a large portion of the ground had been cultivated, but would not produce a crop this year. He would observe, with reference to the recent Act of Parliament referred to by Mr. Lobb, that he thought that gentleman took a rather erroneous view of the intention and effect of the regulations by which the Board of Trade proposed to carry out that Act. The Board of Trade having done him the honour to refer to him occasionally in the administration of that Act, perhaps he might venture to say a few words upon the subject. In the first place, he thought it was a misconception to suppose that when Parliament passed that Act they had the intention of making it practically amount to a confiscation of the existing fisheries of the kingdom. Of course where a large public fishery existed, private individuals or associations would be glad if they could readily obtain exclusive possession of it. An oyster fishery was a valuable thing, but it was by no means clear to him how such an appropriation would benefit the public, unless

it could be shown that it would result in an increased supply of oysters. Whether the fishery were worked by a corporation, by private individuals, or by a company, this was the only question to be considered. The object of the Act, as he understood it, was more particularly to promote the creation of new fisheries in this country. As Mr. Lobb had stated, a portion of the coast off Hayling Island was admirably adapted for the cultivation of oysters on the French system. He understood that that was a private undertaking, and required no parliamentary sanction; but supposing it had been public ground, he thought that would have been a proper opportunity for applying the provisions of the Act, so that those who undertook to cultivate that oyster ground might have security in the property they created. With regard to the alleged excessive stringency of the regulations, at all events this had not deterred persons from making applications under the Act, because a number of them had been made, and he hoped it would be found consistent with the public advantage to grant some of them. The administration of that Act had been conferred upon a Board whose liberality and courtesy in dealing with all sorts of commercial matters which came before them was notorious, and one great advantage which oyster cultivation would receive from the new Act was, that the management of the foreshores was transferred from the Woods and Forests to the Board of Trade. That Board had already evidenced its intention of exercising the powers granted by the Act in a liberal spirit, and there was reason to believe it would eventually be a great success. He hoped it would ultimately lead to a great diminution in the price of oysters, for that was the practical point which they all wished to arrive at.

Mr. LOBB said, with regard to the success of the Hayling oyster grounds, the idea was originally to commence operations with a large area of forty or fifty acres, but it was found if the company did that they would waste a year; therefore, some saltings near the beds were purchased, and they commenced at once with a pond of four acres and the adjacent saltings of eight acres; but of the pond of four acres there was only time to get one acre ready, as the bottom was muddy and had to be made firm. First of all sand was thrown over it, then about eighteen inches' depth of shingle, and then, about two feet from the bottom, a series of hurdles were placed; the oysters were laid upon the shingle bottom. On the 14th of June they showed signs of becoming "sick," and on the 16th July following the whole of the under surfaces of the hurdles were covered as thickly as they could be with spat. As he had stated, only one acre out of the four had been as yet cultivated; the remainder was still muddy, and if the spat fell upon the mud it was choked, but he did not suppose any of the spat had fallen upon the mud, because it naturally sought the shingle and hurdles. The value of the spat thus deposited had been variously estimated at from £2,000 to £12,000. The value put upon it by the company was the former sum, but when the oysters were sold next September twelvemonths the real value would be ascertained. The area which would be prepared ready to receive the next spat was about 35 acres, and if the success on that more extended scale was as great as it had been last year on the single acre, the company would have every reason to be satisfied. With regard to the relative temperature of the water at Hayling and Aroschon, no doubt at the latter place it was higher. The average temperature at Hayling in summer was, in the day-time—maximum, 67° Fahr.; minimum, 50°; mean, 62½°. With this steady temperature, there could be no doubt of the success of the operation. Hayling was very warm; it was much protected; the Isle of Wight lay in front of it; it was free from stormy weather; indeed, there was nothing at all inimical to oyster culture. With respect to the administration of the Act of Parliament by the Board of Trade, he hoped the remarks he had made on this subject would not be considered out of place, but

he had no idea, when he undertook to write the paper, that so eminent a man as Mr. Osve would occupy the chair; the chairman, however, was able to correct him, if he had been in it. The memorials for the establishment of oyster fisheries forwarded to the Board of Trade had hitherto been unsuccessful. There were three or four more to be sent in, and he hoped these would be more fortunate. The Blackwater fishery was an instance in which he thought much good might be done by the intervention of the Board. It was 15 miles in length, and, at present, was almost entirely destroyed by reckless over-dredging. What he wanted was that these grounds should be handed over to people who would take care of them, and protect them from over-dredging so as to greatly increase the produce, and to the benefit of the public. The Whitstable bed was a magnificent one, worth many thousands a year, because it was protected; but if this had been allowed to be over-dredged, as had been the case in other instances there would have been scarcely an oyster left, or a spat remaining. It had been the same both in France and in England, wherever a natural bed of oysters was discovered, it was dredged bare. The case of the Solent, one of the most magnificent beds in the kingdom, was now a mass of sludge. It had been dredged till there was not an oyster left, except in one place, where the rush of water was so great that it kept the bottom clean, but all the other beds were one mass of sludge. It was the same with the Emsworth fisheries; there was no trace of oysters there this year, and every oyster was removed in a year or two which ought to have afforded several months' dredging.

The CHAIRMAN said there were certain points in Mr. Lobb's able and interesting paper from which he had agreed to a certain extent, but these were matters of detail rather than of principle. He thought the general result of Mr. Lobb's statements had been to show that on principle and on general grounds, the action of the Government had been entirely right in this matter. Mr. Lobb stated that the Commission which sat on the question was deceived by the evidence given before them, mere guess-work; but those Commissioners conducted their investigations for more than two years, and when he mentioned the name of Professor Huxley as one of them, it was a sufficient guarantee that great care and scientific knowledge were exercised in the investigation. He might say, having been the president of a commission which went to France last winter to negotiate a Fishing Convention with the French Government, he found that the report of the commission which Mr. Lobb had spoken of and the whole of the evidence had been translated into French, and was considered in France to be a very valuable document. It was not correct to say that he (the Chairman) was the stepfather of Mr. Milner Gibson's Bill, and that he took it up at the third reading. The fact was, the Bill had been read a second time only, and he introduced several alterations in committee before the Bill passed the House, and he thought some of them would go far to accomplish what Mr. Lobb had expressed in his paper. The Act which Mr. Lobb said, was very vague, but Acts of Parliament were generally very vague. They laid down certain principles; it was impossible to go accurately into details. It was not correct to say that the first batch of memorials under this Act were refused without inquiry. Those memorials came before him, and great inquiry was made upon them. No doubt Government was anxious before coming to a decision to settle some definite rules on which to act, and it was no great blame to the Government if they sought for further information before taking action in a matter which was quite new, for the Act was only passed in July last year. As we were only now in March of the following year he did not think any extreme delay had taken place. He saw in a little book written by the author of the paper,

was stated in the preface that it would probably take twenty years to effect the objects he had in view. If that was so—and probably Mr. Lobb was right—he (the Chairman) did not think the few months that had elapsed since the passing of the Act should be regarded as a waste of time in proceeding cautiously before granting applications that had been made under this Act. They must know in the first place that the Crown rights upon the foreshores of the sea or tidal waters between high and low water marks, which had been under the administration of the Office of Woods and Forests, had been lately transferred to the Board of Trade; but the ownership of the Crown must be regarded as a mere trusteeship for the public. The Crown should protect the rights of the public in them, and if it granted them exclusively for certain terms of years to particular persons applying for them, his must be done in the interests of the public. There were certain applications which Mr. Lobb had specially referred to—viz., for the Blackwater and the Solent. Both these were very large areas, and those gentlemen who applied for the Solent wished to have the entire control over that large sea, not only for the cultivation of oysters themselves, but to give licenses to other people to cultivate them; or, if they thought it necessary, to shut up the fishery altogether for two years, much as the Dutch used to burn nutmegs to prevent them becoming too cheap. These applications were naturally refused, because the areas were too large. The object of the Act was to do as far as possible what the French had done on their coasts. What the French desired was, not to bring large companies to bear upon these great areas, but to bring individual enterprise, or small associations of men to bear upon them. It was considered that there was a dog-in-the-manger feeling on the part of large companies. They collected all they could gather for themselves and wished to keep out all others. He spoke on this subject generally: he had not any individual case on his mind. In the interest of the public no doubt small areas should be given. The French granted very small allotments, and the Minister of Marine informed him that his view was to let every individual have his own private oyster park, as it was thought under that system the culture would be carried out more satisfactorily than if the trade was monopolised by large companies. He thought Mr. Lobb had misunderstood the first clause of the general principles which he had quoted, which stated the concessions under the Act to be “Appropriations of moderate areas of unprotected sea-bed, or foreshore, for the establishment of new fisheries or local depots.” Mr. Lobb thought very naturally that nobody would be likely to cultivate anything which was quite certain to produce nothing. It would not be common sense to do so; but in this case he (the Chairman) thought the word “unproductive” meant what was not now producing anything, and as a sort of defence of this expression he would quote the words of the paper with regard to the Emsworth fishery, in which Mr. Lobb said, “Unless it becomes worth the while of companies or private individuals to cultivate these ‘unproductive’ bottoms, it will never become re-established.” What Mr. Lobb there meant by the word “unproductive” was precisely what the Government meant by it in these general rules. It simply meant that which was not now producing anything, either because it had been over-dredged and destroyed, or because it had never been tried. Mr. Lobb had shown that there were parts of the coast which were considered hopeless for the cultivation of oysters, because there was nothing naturally for the spat to take hold of, but he had shown them to-night that if they laid down tiles or hurdles they enabled the spat to take hold. That was exactly the point the Government took. On the north-west coast of England there were, long before this Act was passed, artificial oyster fisheries, which failed for want of protection by law. This was sought to be remedied by

the Act of last session; and the Bill now before the House of Lords gave the same protection from depredations in the case of oyster beds as was now afforded by the game laws in the case of game on an estate. In former days, if they caught a man “red-handed” taking oysters from a bed, they could punish him for the theft; but, if he was five yards away from the bed, they could not ask him where he got the oysters, any more than, under the old game laws, they could demand that a man should account for the possession of any pheasants or partridges found upon him. Therefore, it was clear that being the state of the law, there was little inducement for persons to spend money to form these oyster beds, because there was no legal protection to the property. In this respect the Act of last session was not entirely satisfactory, inasmuch as, while it protected the fisheries formed under that Act, it left those which were formed before the passing of the Act without this remedy, and he thought the Hayling Company complained of this very justly; and, though he (the chairman) did not see his way, at the time Mr. Lobb spoke to him on the subject, to remedy the defect, he had seen it since, and he hoped he had now done it effectually. As to the general question, what was the object of this legislation, he was aware it was popularly considered better to leave everything free—that fish should be left free to those who could catch them, the supply being practically inexhaustible; but the case of oysters was no doubt different. Mr. Lobb had stated very truly that the oyster beds on our coasts had been over-dredged. But what was the reason? Simply because the demand for oysters was much greater than it used to be. Persons of his own age recollected the time when barrels of oysters were sent from London by the coaches into the principal towns; but now every little town got its supply of oysters fresh by railway, and the consumption of them was enormous. We might have prevented the over-dredging in the same way as the French had done, but we must recollect the difference between a paternal government and our own. It was, moreover, remarkable that though the French had been very strict in their fishery laws, while we have been rather lax, notwithstanding this, the price of oysters in Paris was higher than in London. The only way in which we could stop over-dredging in the public beds was by a strict enforcement of the fence-months; but if there were considerably too many dredgers during the open months of the year, the beds were dredged bare. What was the remedy for this? Mr. Lobb had pointed to it in his little book, in which he laid it down as an axiom that the natural oyster beds of the United Kingdom were nearly exhausted, and thus “private breeding beds have become an actual necessity.” That was the whole case. Mr. Lobb and himself were entirely agreed on this point—that we could not rely on the public beds any longer, but we must come to the private beds, and that every possible facility ought to be given for the formation of such beds. At the same time it must be recollected that there are public beds, and we must respect public rights. It might do for a paternal Government, like that of France, to say they would take upon themselves to do what they considered best for the public generally; but in legislation we could not always do that, and must often respect existing rights however absurdly they operate. In the case of the Blackwater there had always been a public trade, and the fishermen had been in the habit of dredging it year after year; but if Government were at once to divide the whole of the Blackwater amongst different companies a considerable amount of public discontent would be caused. Therefore, in a case of this kind, as in many others, legislation must be based upon compromise. They must take public opinion with them, and must feel their way to every step before they took it, particularly in so delicate a matter as this. He had detained the meeting for a considerable time, but, holding the position he did, he thought it proper he should explain as carefully as he could the points on which legislation

on this subject had been based. He had probably eaten oysters in as many parts of the world as most people. He had eaten those which hung on trees in South America; he had also eaten the enormous oysters of North America, two or three of which were sufficient to make a great dish of soup; he had also eaten the classic oysters of Baïa, near Naples; and the green oysters of Ostend and other places; but he must say, in all his experience, he had found none equal to what were known as "natives" in this country; and his own personal feeling, as well as the interests of the public, would lead him to desire to increase as much as possible the supply of so highly valuable and popular an article of food. He would now propose a hearty vote of thanks to Mr. Lobb for his most interesting paper. He felt personally obliged to that gentleman for the remarks he had made upon legislation, because they had given him an opportunity of explaining, as clearly as he could, and without the slightest desire to say a word against what Mr. Lobb had written, the objects and purposes of recent legislation, as bearing upon this subject.

The vote of thanks was then passed, and acknowledged by Mr. Lobb.

Proceedings of Institutions.

SHERWOOD MUTUAL IMPROVEMENT SOCIETY, BATTERSEA.—The last report says that the number of members has greatly increased during the year. The course of fifteen lectures which have been delivered was most successful. The committee beg to express their thanks to Mr. G. Payne for his instructive lecture on chemistry, also to Mr. Roberts, sen., for his interesting displays of dissolving views. The library now consists of nearly 3,000 volumes; a new case has been made for them, and the whole insured against loss by fire. A catalogue has also been prepared. Various classes have been formed, viz., a drawing, vocal, and an elementary class. The two first were successful, but the last was not well attended. A mutual arrangement was made with the Young Man's Christian Association, Wandsworth, for an exchange of a limited number of tickets, which enabled many of the members to enjoy the privilege of hearing a very excellent course of lectures (in addition to their own), of which many availed themselves. The balance-sheet shows that the receipts have been \$266 7s. 2d., and that there is a balance in hand of \$68 16s. 1d.

ENGLISH MEDICINAL RHUBARB AND HENBANE.

By RUFUS USHER, Esq.

Although the introduction of medicinal rhubarb into England is dated by Parkinson as far back as 1629, no real experiments in its culture and preparation for medical use appear to have been made till 1762, when a quantity of seed was sent from Russia, by Dr. Mounsey, from which period till about 1800 it was successfully grown in small quantities by many scientific men, after which it was cultivated at Banbury on an increasing scale, and is now known in the commercial world as a general article of trade; and not only is it consumed in considerable quantities in this country, but it is exported largely to various parts of the civilised world. The origin of the plantations of rhubarb in my possession, and now extending over forty acres, will be best traced by the following extracts from the "Transactions of the Society of Arts." In 1789:—"The Society, in consideration of his merit, and to promote as much as in them lies the growth and cultivation of so valuable a drug, voted their silver medal to Mr. Hayward, as a bounty." In 1794:—"The following accounts and certificates respecting the growth and cure of rhubarb having been received, the gold medal, being the

premium offered for cultivating the greatest number of plants, was adjudged to Mr. William Hayward, of Banbury." The following is the testimony of Dr. Pennic:—"In 1789 Dr. Hayward obtained a silver medal, and in 1794 a gold medal, from the Society of Arts, for the cultivation of English rhubarb. Dr. Hayward died in 1811, and the plants were purchased by Mr. P. Usher."

As a proof that even at this early period of its cultivation English rhubarb had obtained the confidence of scientific men, it may be stated that, in 1795, rhubarb of British growth was used at St. Bartholomew's, St. Thomas's, and Guy's Hospitals, and was being experimented on at several others. According to the testimony of Sir Alexander Dick and Dr. Hope, of Edinburgh, in 1784, but little rhubarb was used by the apothecaries of that city but what was produced in Scotland, and it was considered in no respect inferior to Russian. About the same time English rhubarb was put to a severe test at Bath, by Drs. Falconer, Parr, and Fothergill, all of whom attested its merits. Dr. Falconer remarked, that two of the specimens submitted to them answered in external marks the character of the foreign; that they were rather inferior in delicate taste to the Turkey, but superior in other respects to East India. In 1810 Dr. Thornton, then lecturer in botany at Guy's Hospital, referring to the encouragement given to the cultivators by the Society of Arts, makes these remarks:—"This account may serve to show both the ardour of this respectable Society in encouraging the growth of this useful article and the persevering industry of some gentlemen in overcoming all the difficulties attendant on introducing a new plant into cultivation—finding out the means of curing it as an article for extensive sale, and overcoming the prejudices of such as cannot persuade themselves that drug of British growth can bear competition with what is sent us from foreign countries."

If at a later date the prejudice against English rhubarb having increased, there must have been other causes than those existing in the first introduction of the plant. One cause of the subsequent change in public opinion may have arisen from the partial introduction of several varieties of the plant. From the earliest period in its history there appears to have been a confusedness in the evidence as to its real character; and whether foreign rhubarb is produced from the *Rheum palmatum*, or the *Rheum undulatum*, yet remains an unsettled question. As far as this question relates to rhubarb grown in Great Britain, the stronger probability is, that, after it was imported, several varieties were produced by repeatedly propagating from seed, when a discrepancy was observed, at variance with the earliest descriptions recorded. To show the extent of those changes, I may remark that in the last instance in which I noticed the effect of seedling cultivation, about thirty years since, I found the stalks and leaves more than double the size of those produced from off-sets, a circumstance sufficient to account for the introduction of such varieties as the Victoria and other large sorts now so common in our gardens, and which, when propagated from seed, still keep working change upon change. So convinced have I been for a long time of the injurious tendency of this system, that I have studiously avoided the use of seed altogether; and the plant has so far receded to its original type, that not one has produced ripened seed during the last twenty years. It is a fixed trait in the cultivation of medicinal rhubarb, as it is in most bulbous plants, that if produced from off-sets only, it ceases to produce seed, and if raised from seed each succeeding generation produces seed also, adding variety to variety almost indefinitely. Assuming, as an incontrovertible fact, that the plant has now for such a lengthened period been propagated from off-sets as to be incapable of bearing seed, it will guarantee the conclusion that if, during a number of years, when its cultivation was pursued by a larger number of growers, for the purpose of making experiments, and each one, in haste to enlarge its growth,

resorted to seed propagation, it degenerated from external causes, it is equally logical to infer that, the causes having ceased which led to its deterioration, it has now regained its specific distinctiveness, and is not likely to diverge again into any transition from its central type. It is thus quite possible to account for the previous deterioration of the plant for medical uses, which caused the strong prejudice existing for many years against it, and some remaining doubts are still expressed respecting the real properties of English rhubarb; but that a powerful reaction has taken place in its favour since the plant has been restored to its primitive form of development, there is most ample testimony, not only in the increased demand for it at home and abroad, but in the evidence of eminent medical practitioners. In addition to the improvement which became apparent in the plant by the entire exclusion of seedlings, an important change has been effected in the mode of drying, by exchanging a high artificial temperature for a more gradual one; the process in the first stages being effected by the application of a strong current of atmospheric air, which has not only greatly condensed the root, and rendered it less porous, but has given it an appearance approximating more closely to foreign.

The progressive but certain destruction of all former prejudices existing against the use of English rhubarb, may be adduced from facts much stronger than theory. The first is that as recently as 1845, the extent of land appropriated to the cultivation of the plant did not reach ten acres, whereas now it has reached upwards of forty acres, and even this is quite insufficient to supply the foreign demand for trimmed English rhubarb. If the home consumption of this drug had remained stationary, the export trade alone would have afforded every facility for extending the plantation, a fact most strikingly shown by the article being sent to ports, such as Odessa, from which East India rhubarb is sent to Great Britain.

Even where regulations of the most stringent character have been put in force to prevent the use of either inferior or adulterated drugs, English rhubarb has passed the ordeal in safety. The following is a portion of one of the statutes of the United States of America, entitled, "An Act to prevent the Importation of Adulterated and Spurious Drugs and Medicines." Thirtieth Congress, Chapter 70th, date 1848; Section 1st provides—"That from and after the passage of this Act, all drugs, medicines, medicinal preparations, &c., imported into the United States from abroad, shall, before passing the Customs-house, be examined, as well in reference to their purity and fitness for medical purposes, as to their value and identity specified in the invoice." Section 3rd provides—"That if, on examination, any drugs, medicines, medicinal preparations, whether chemical or otherwise, are found, in the opinion of the examiner, to be so far adulterated, or in any manner deteriorated as to render them inferior in strength and purity to the standard established by the United States, Edinburgh, London, French, and German pharmacopoeias and dispensaries, and thereby improper, unsafe, or dangerous to be used for medicinal purposes, a return to that effect shall be made upon the invoice, and the articles so noted shall not pass the Customs-house, unless, on a strictly analytical character called for by the owner or consignee, the return of the examiner shall be found erroneous." To carry into effect the provisions of this Act, qualified examiners of drugs were appointed, at salaries varying from one thousand to sixteen hundred dollars per annum, at the ports of New York, Boston, Philadelphia, Baltimore, Charleston, and New Orleans.

A large proportion of my trimmed rhubarb for several years passed through the hands of Messrs. David Taylor and Sons, for shipment to the American market, where it became a regular article of commerce.

From the year 1855 to the present period the demand for English rhubarb has far exceeded my means of supplying it; and the ratio in which the increasing demand is taking place far exceeds the propagating

capacity of the plant. The period when the rapidly increasing demand for export took place, was that immediately succeeding the investigation of the question by a Committee of the House of Commons, during the sessions of 1855 and 1856. It will be recollected that a committee was appointed, of which Mr. W. Scholefield, member for Birmingham, was chairman, to invest the question of adulteration of food, drink, and drugs. During the sitting of this committee a large number of witnesses were examined on the question of English rhubarb, with varying results as to the individual opinion of the parties examined. Some, amongst whom may be named Dr. Hassall, contended it was practicable to carry out a system of absolute purity in drugs and chemicals; whilst others, with equally practical views, contended that a classification as to the quality of these articles must always exist. I need scarcely say that the evidence adduced on the question of the adulteration of drugs, as of other things, was very conflicting and inconclusive. At the commencement of the second session occupied by the committee in this investigation I was summoned, on the 5th March, 1856, to give evidence on the long-voiced question of English rhubarb; but both as regards my own and the evidence of other parties, which fully shows the importance of the question raised, I can do no more in this paper than refer the reader to the Blue Book for an exposition of the whole affair. But to show that my position was not damaged by the result, I quote the following words of the Chairman of the committee at the close of my examination:—"If it be represented to the committee that English rhubarb is sold as an adulterating article, and is of a very inferior quality to foreign, that is a mistake; for medical men attribute very important medicinal qualities to English rhubarb, and it is consumed in some important public establishments, and is held by very high medical testimony to be an exceedingly useful medicine." One of the public establishments referred to here is the London Hospital, where English rhubarb alone had then been used for a number of years. The inquiry carried on before the committee was kept alive, to a great extent, owing to what was represented to be the extreme difference in the money value between foreign and English rhubarb; and it was on this point that I had to complain of some unfairness. One witness stated the difference as great as between 11s. per pound on the one side and 4d. on the other. Here the retail price of foreign was quoted, the average wholesale price of China rhubarb for the 12 months previous being only 5s. 6d., whilst as to quality, the maximum of one was set up against the minimum of the other, as I was, at the very time the evidence was taken, entering English rhubarb for shipment at 2s. per pound to Messrs. Taylor, Brothers, Mark-lane.

A great error, almost invariably committed in passing judgment on any article of supposed inferiority, is to judge it by an improper standard. This has been strictly so in the present instance. To show that one sample is of bad quality, is certainly not proving that another is good; but when an attempt has been made to prejudice the public against the use of English rhubarb, it has sometimes been done by putting it into competition with the very choicest specimens of the foreign article; and I believe that all the comparisons, including the testimonials also, have been made on this principle. If it is true that a great difference exists in samples of drugs generally, it is yet more so in those of foreign rhubarb. It is well known that but a very small proportion of imported rhubarb is of the best quality. This fact did not escape the notice of Dr. Pereira. He remarks, that when China or East India rhubarb arrives in London, it is hand-picked, tared, and sorted into three qualities—bright and sound, dark and horny, and worm-eaten. He adds the following evidence on this point:—"In 1840, when China rhubarb was very scarce, a quantity of foreign rhubarb, imported from Calcutta, was sold, some at 4d. and some at 1d. per pound." As the evidence arising from dissimilarity of price has been used as an

argument to show the inferiority of English to foreign, the following facts deserve notice:—In the years 1846 and 1847, there was a very large quantity of foreign rhubarb disposed of, amounting to several tons weight, and such was its general quality and condition, that the terms made use of to designate it, with the prices realized, were as follows:—Old and bastard, at 3d. to 1½d. per pound; old brown and rotten, 1d. to 4d.; rotten and damaged, 3d. to 5d.; brown, old, and perished, 1d. to 6d. During these periods large quantities of English were sold at from 1s. to 2s. per pound. Thus it is seen, that if the maximum price of foreign is higher than English, the minimum price of English is higher than foreign. Whatever, therefore, may be supposed to be the relative difference between English rhubarb and the best specimens of foreign, it is clear that, owing to the very imperfect method of curing it in those countries where it is produced, there is invariably that strict uniformity of character in the one which is as invariably wanting in the other.

One leading question relating to this most important medicinal production yet remains to be solved at some future period, namely, whether the plant from which foreign rhubarb is produced is the best that could be selected? Judging from the very great variety and very interesting specimens in the possession of Dr. Hooker, all of them distinctly differing from each other, it would appear doubtful if the foreign cultivators have made such researches and instituted such experiments as would lead to a judicious selection of the best sorts. It is also highly probable that, if offsets could be obtained from a number of the several varieties of the plant produced in Tartary and elsewhere, we might acclimatise some yielding higher medical properties than any yet cultivated in Great Britain; but as the means of obtaining them is entirely out of my power, I can only say, that if I could be assisted in procuring them, I should feel great pleasure in carrying out such a series of experiments as might ultimately render an important addition to the medicinal productions of the nation.

My attention has recently been called to the subject of the preparation of that very important medicine, tincture of henbane, in consequence of the very erroneous views entertained with regard to the character of the plant, and to the somewhat scanty, if not imperfect directions, contained in the new pharmacopœia respecting its preparation for use. It is out of my province altogether, as a grower and preparer only of medicinal plants, to call in question the correctness of the pharmacopœia from any other point of view than that of an omission. The directions given in this work for the preparation of tincture of henbane are, to use "the leaves and branches of the indigenous biennial plant dried, when about two-thirds of the flowers are expanded." Now I believe that almost every wholesale druggist in the kingdom will endorse my statement, when I say that up to the year 1862 but a fractional part of the tincture of henbane prepared in this country was made from the blossoming biennial plant; a circumstance not so much reflecting discredit on those who prepare and supply the article for use, as arising from the absolute impossibility of procuring the material to carry out the instructions of the pharmacopœia. If the question is asked, why the blossoming biennial plant had not, up to that period, been produced in sufficient quantity to supply the demand, I reply that, owing to the almost invariable attack made on the plant during the autumn and winter months by the wireworm, slug, and other destructive visitants, but a small proportion survives till the ensuing spring. Either the root is bitten through in several places or the bud entirely consumed. To this it must be added, that of the plants which escape this ordeal, when they have reached that stage of their development pointed out in the pharmacopœia, namely, "when two-thirds of the flowers are expanded," the

foliage is very scanty, and it will only pay the producer at a high price.

Through some erroneous impression, that has long existed, and still continues to exist, respecting this very important plant, the first year's growth is spoken of as the annual, than which nothing can be more palpably wrong, as the two articles, when prepared for use, vary essentially in their external appearance as in their constituent properties; applying this simple test only, the annual plant, when dried, consists both of leaves and blossom, whereas the first year's growth of the biennial must necessarily consist of leaves only. Assuming that, when the second year's growth of the biennial plant cannot be procured, recourse must be had to the first year's growth as a substitute, the pharmacopœia should have made known the comparative strength of the latter. No objection could have been made to such directions, when it could be shown that a second-class article must of necessity supplant a superior one, as occurs, doubtless, not only in this but in many other medicinal preparations. If, in the case of the two separate articles now under consideration, the same instructions are carried out, namely, to use two ounces and a half of the dried plant for a pint of tincture, and as should prove to possess two or three times the strength of the other, it assumes a serious aspect in the administration of so very important a medicine. We require a new definition altogether of the plant when dried for use. Instead of making two divisions only, as at present, annual and biennial, it should be classified as follows:—

Biennial henbane of second year's growth.

Biennial henbane of first year's growth.

British annual henbane.

German henbane.

This would at once simplify the question, and prevent those erroneous views which have very widely prevailed amongst all parties concerned in its preparation and use. It will be seen that I have arranged the above classes in the order of their value. The two last-mentioned—the British annual and the German—although used extensively, are so thoroughly undeserving notice, that they require mention only to guard the public against their use altogether. Of these two, the British annual is perhaps preferable to the foreign, and its appearance, unfortunately, approximates sufficiently close to the second year's growth of the biennial plant to enable the vendor to pass it as such; but if no other criterion existed than that it possesses no flavour, or aroma, that would be sufficient to detect the imposture. Independently of this test, the leaves will be found much shorter; and occasionally will be seen a pure primrose blossom, which never occurs in the beautifully streaked blossom of the biennial; but the very fact of the appearance of blossom in the sample, that blossom being generally so much like the blossom of the biennial, leads to the very erroneous conclusion that it is the same plant.

Owing to the extreme price which the dried biennial plant of the second year's growth has realised in former years, the consumers have not given that encouragement to its production which its intrinsic value merits. The great difficulty, however, which has thus been felt of very recently—that of not being able to obtain a supply except at a most exorbitant price—is now to a great extent obviated. From a long, careful, and continuous study of the cultivation of biennial henbane, I have at length so far succeeded in preserving it from the attacks of insects, to which it is ordinarily subject, and have to such an extent economised the system of drying the plant, as now to bring the price within reasonable bounds, and to leave those who prepare the tincture of this valuable plant without any just excuse for using an inferior article.

This is not an age in which scientific research can be long baffled in its inquiries; and as the articles in ques-

on will be placed before the public in the Paris Exhibition of 1867 (class 44), no more will be anticipated from their inspection by a competent tribunal than the closest scrutiny will justify.

Fine Arts.

NATIONAL PORTRAIT EXHIBITION.—The exhibition of last year is officially declared to have been "very successful." "During the 18 weeks it was open it was attended by 73,000 visitors." In order to record the general appearance of the galleries, and the position in which the pictures were hung, 77 photographic views have been taken and published of the bays of the exhibition. And, for the purpose of affording to artists and others examples of court costume, nine photographs, on a large scale, have been executed from the most important portraits of the Tudor period.

PHOTOGRAPHS TAKEN FOR THE DEPARTMENT OF SCIENCE AND ART.—The arrangement, of which we have already given notice, for the sale of these photographs by the Arundel Society, is now complete, and a classified list has been published. The catalogue comprises photographs from national portraits and miniatures, cartoons and drawings by Raphael and Michael Angelo, Holbein drawings at Windsor, works by Mulready, "Liber Studiorum," by Turner, Italian sculpture, &c.; also objects of decorative art in precious metals, porcelain, crystal, enamel, ivory, &c., belonging to, or placed on loan at, the Kensington Museum. The entire series comprises upwards of two thousand photographs. It is also announced that "Artists, manufacturers, and the public generally, may obtain negatives from the objects in the permanent collections in the Art Museum," at a rate of charge ranging from 10s. to £1 10s. Negatives are also taken of all works on loan, and two prints presented to the proprietors. Photographs which may be deemed calculated to promote art education, are circulated among the schools of the kingdom. The general intention of the above arrangement is to promote the knowledge of art throughout the country. Full information can be obtained either at South Kensington Museum or at the offices of the Arundel Society, in Old Bond-street.

Commerce.

THE NUTMEG.—For many years the Straits settlements were famed for the cultivation of the nutmeg. At Penang, in Province Wellesley, at Malacca, and at Singapore, the cultivation of this spice seemed to be attended with very gratifying success. Young trees were set out in every direction in plantations, and everywhere they appeared to thrive, and to yield a very fair supply of nutmegs. The nutmeg tree has a pretty appearance, running up to a height of from 25 to 30 feet, with numerous branches shooting directly out at right angles from the stem, and the leaves are of a fine green colour at the top, and of a paler hue on the under surface. Strange as it may seem (says the *Produce Markets Review*) the cultivation of this spice tree has apparently declined. In fact, of late years, it has become a losing business. Everywhere through the Straits it is now pronounced a failure. As a substitute for this branch of industry, the planters are setting out their lands with cocoa-nuts. Whether the substitution of the cocoa-nut cultivation for the nutmeg will prove an equally valuable product is yet undetermined. Of course there are other places where the nutmeg will be still grown. It is said to be indigenous to the Molucca Islands, and to parts of Java. It grows to some extent in Ceylon, almost by the side of the cinnamon and coffee trees. It has been introduced into the Mauritius, and into some of the West India Islands. However much the loss of the

spice trade may be regretted by friends of the Straits, the markets of Europe and of the East will never fail, of course, of receiving their supplies from other places.

Obituary.

MR. JOHN BATHELL, the patentee of the creosoting process for preserving timber, died in London, in the early part of the present month, at the age of 64. He was the only brother of Lord Westbury. *Engineering* states that Mr. Bathell took his idea of preserving wood by creosote from the embalming of mummies, the creosote having the property of coagulating albumen. Coal tar contains a considerable quantity of creosote, and when boiled to expel its ammonia it is called coal oil. The proportion of creosote in this oil is ascertained by mixing it with 10 per cent. of its own bulk of a strong caustic alkaline solution. After shaking and settling, three layers will be formed—the lower layer of caustic alkali, the next, forming from 8 to 18 per cent. of the whole, being creosote, while the bituminous oils float at the top. Mr. Bathell joined the Institution of Civil Engineers as an Associate, March 20th, 1838, but did not become a member. His creosoting patent was dated July 11th, 1838. He took out several patents, including ploughing engines, steel bearings for carriages, and improvements in agriculture. He was at the time of his death chairman of the British and Foreign Railway Plant Company. He was elected a Member of the Society of Arts in 1853, and not unfrequently spoke at its meetings.

Publications Issued.

SUCCESSFUL OYSTER CULTURE. By Harry Lobb, Esq., (*Ridgway, Piccadilly*). Price 1s. This pamphlet gives an account of the success obtained at Ile de Ré, Arcachon, and at Hayling Island, near Portsmouth, by the modern system of oyster culture; with extracts from the *Times*, the *Field*, and other papers. The system carried on at Hayling appears to promise great results, and should be witnessed by all desirous of entering upon this new field of industry.

Notes.

SOUTHERN COUNTIES ASSOCIATION.—A meeting of the Council was recently held at the house of the Society of Arts; present—Viscount Eversley, in the chair; Hon. and Rev. S. Best, Mr. Beynon, M.P., Mr. Clutton, Lieut.-Col. Deedes, Lieut.-Col. Lennard, Mr. Lyall, Sir H. St. John Mildmay, Bart., Mr. Melville Portal, Mr. J. C. Ramsden, Mr. Rigden, Mr. R. J. Spiers, Rev. T. C. Wilks, Mr. Wise; Rev. James Beck and Mr. Shute, secretaries. A considerable number of members were admitted, among whom may be mentioned, Major Aldridge, Knapp Castle, Horsham; Captain B. B. Bartelot, Findon-place, Worthing; Mr. Thomas Bell, the Wakes, Selborne, Hants; Mr. George Blaker, Pilcomb, Hurstpierpoint; Mr. J. Bonham Carter, M.P., Adhurst St. Mary, Petersfield; Rev. G. A. Clarkson, Amberley Vicarage, Arundel; Mr. E. W. Cooke, R.A.; Mr. W. H. Dunn, Inglewood-house, Hungerford; Mr. I. P. Fearon, Ockenden-house, Cuckfield; Mr. A. J. Beresford Hope, M.P., Bedgebury-park, Goudhurst; the Bishop of Oxford; Rev. F. Parsons, Selborne, Hants; Mr. Wm. Saxby, Bottingdean, Brighton; Rev. E. St. John, Finchampstead, Wokingham; Mr. F. Tupper, West Ham, Hurst-green; Mr. Wm. Webb Turner, Chyngton, Seaford, &c. The proposed plan of the show-yard at Hove, and estimate for the supply and erection of shedding and offices, were submitted to the Council by

Mr. Henry Manning, late contractor to the Royal Agricultural Society, and the secretary was authorised to sign a preliminary contract with him for the amount of £587, capable of extension after the 1st of May, should the number of entries render it requisite. In reference to the exhibition of works of art in the Pavilion being kept open by the mayor and corporation of Brighton for a month after the closing of the show of the association, the secretary was directed to inform the mayor that the only guarantee they would require from the corporation for the safe custody of the property handed over to them was what they themselves give to the lenders—viz., that of extreme vigilance. The following stewards of the Brighton Show were then chosen:—Stock: Sir Archibald K. Macdonald, Bart., Mr. George Shackel, Mr. James Singer Turner, and Mr. Richard Woodman. Horses: the Earl of Portsmouth and Mr. T. Pain. Puntetts: Lieut.-Colonel Deedes and Mr. P. S. Punnett. Poultry: Mr. H. F. Stocker and Mr. Turner. Mr. George Darby, of Marklye, Warbleton, was unanimously elected a vice-president for Sussex, in the room of Sir J. Villiers Shelley, Bart., deceased. The Council adjourned to Wednesday, April 10.

Correspondence.

THE GOVERNMENT AND THE TELEGRAPH.

SIR,—I regret that some pressing engagements have delayed my answer to the question put to me by letter, in the *Journal*, by Mr. Hawkins Simpson, i.e., whether I think that, either at the present time or in future years, it would be for the public interest to prevent the despatch of telegrams by private enterprise; or, in other words, do I "wish the Government to monopolise the use of electricity for the purpose of conveying information to the public." I conceive that, on a due consideration of the tenor of my paper, it might be perceived that my chief wish is that the Government should make free to us, the public, the full use of our own establishments—should make free to us the means of communication which science has given us—and should free us from exactions on our necessities by irresponsible traders, who, under the guise of competition, have obtained joint and sometimes separate monopolies of the necessarily imperfect and necessarily dear use of those means. I believe that the conveyance of telegraphic messages, as well as the conveyance of letters by post, may and ought to be so conducted, as a responsible public service, as to leave no chance for private trading competition, and no need of any penalties for protection against it.

There are now penalties on our statute books against the sending or conveying any letters by post, but they appear to have fallen into disuse. Nevertheless, we know that on occasions of emergency persons do send letters, tied up as parcels, by railway or by coach, to insure a special delivery earlier than is provided by post, and I think that—except, perhaps, for ocean transit, for which heavily subsidised mail packets are provided—all persons should be left free to do so, the occasions for using the privilege being comparatively few, and the necessary extra charge being itself a sufficient protection against any evasion of moment against the revenue. Moreover, the entire freedom of conveyance should serve as a stimulus to the public servants, so to improve their deliveries at all points for payments as for a service, as to leave private speculators no chance of doing anything the like for any profit over and above the actual cost of the service. I therefore consider that penalties are a remnant of conditions of protectionism, from which, as engendering stagnancy and slowness, the postal service should be purified. And so with telegraphic communication. Private individuals, manufacturers, traders, and gentlemen should be left free to carry telegraphic wires over their own lands or premises, or over other where they can

obtain way-leaves, and they should be allowed a payment of a fair rent, to have separate wires over the public bearers, or to have connections with a public postal stations (on the like terms as private letter boxes) as they may find to their advantage.

Amongst other communications I have received in support of the views set forth in my paper, is one in which I cite the following common illustration of its important benefits derivable throughout the country from the proper application of the principle of administrative consolidation to the matter in question:—

"Between here and London we have to traverse 17 telegraph companies' lines, and of course any fault always attributed at this end to the main company. The agent here is a house agent, and the telegraph is useless to any one telegraphing a private message about a house to be let or sold. At the last election one party had to send their messages five miles by a messenger to forward them by telegraph, thus diminishing considerably the number of messages sent. In many places, as it is here, the post office is in a shop, and the telegraph was added to the post office, there would be sufficient employment for a postmaster without the shop, or he might be made the collector of taxes, and do that during the less busy hours of the day—*viz.* in the middle of the day,—usually the best time for collecting taxes. If, then, these offices were united, and given to one competent man, the work would be done much better than it is at present, when three offices are given to three incompetent men. The officer might be made also the assessor of property for house and property tax, and, being a government officer, he would have no motive for divulging any of the facts, but rival tradesmen have a keen motive to do so."

I should have mentioned the frequent need of the transmission of messages over the lines of separate companies; and their repetition by different clerks as a common source of mistakes; and the conveyance of the messages by hand from one company to another as a necessary occasion of delay, as well as of extra cost.

I consider the utilisation of our 10,000 postal establishments, and of the services of our 20,000 letter-carriers and postal servants for the transmission of money-orders (which I might have mentioned as one service that might often be rendered by postal telegraph), and for the collection, care, and payment of savings, as well as for the payment of annuities, to be one of the most valuable public improvements of our time. But I must take occasion to declare that greatly as our postal service has been improved, there is yet much to do with it in the application of correct principles to keep it up with the advances made upon its own great lead in uniform penny letters in various continental States. Not only in Switzerland, but in other States, a halfpenny letter post has proved to be remunerative. In Hanover, and I believe in some other States, there is a farthing post. In Belgium our *Journal*, for which we are charged a penny, would be delivered for a halfpenny, and so with newspapers and any sheet of printed matter. The charge for the carriage of books is double what it ought to be. With charges reduced (according to the principles we have contended for in this Society) parcels in Hanover are frequently as numerous as letters. In Switzerland, by the adoption of the same principles, the postal parcels have largely advanced; and by these cheap postal deliveries, which separate traders could not accomplish, the railways gain, as we said they would do, by an amount of goods traffic in bulk which otherwise they would not have. Our postal regulations for the conveyance of trade samples, at a fourfold rate of eightpence per lb., are made in a dark spirit of protectionism against parcels in general, and on a principle of exactions on occasions from which the whole service ought to be purged.

Without presenting it as the most advanced example, I adduce the following account, sent me by a relation resident at Zur'—

present postal system,

including telegraphs and parcels, to which Switzerland owes so much of its late commercial and social progress. This account I would commend to the special attention of chambers of commerce, as a most important subject for their consideration, and to retail dealers in the country, as well as to wholesale houses in towns.—I am, &c., EDWIN CHADWICK.

"The largest sized parcel that can be sent by our post is 120 pounds.

"Books, if above 500 grammes (1 lb. 4 oz.) pay as parcels, according to weight or value.

"Parcels (of weight and value) are taxed in Switzerland according to the distance they have to run (the shortest post road being measured). We distinguish weight and value parcels.

"Weight parcels, up to 10 lbs., pay for every 15 English miles 2 centimes, or rather less than a farthing for every pound weight (an English shilling = 125 centimes); and to this is added a ground-tax of 10 centimes (one penny). For weight parcels above 10 lbs. the first 10 are charged as above stated, and 1 centime is added for every additional pound and distance (a distance is equal to 15 English miles).

"Value parcels up to 1,000 francs (£40) pay for every 15 miles (or 1 distance), and every 100 francs 2 centimes (less than a farthing), and to this is also added a ground tax of 10 centimes (one penny). Value parcels above 1,000 francs (£40) pay as above for the first £40, and then are added 1 centime, or half a farthing for every 100 francs (or £4) and distance (15 miles).

"The minimum of a weight or value parcel is, up to 15 miles, 1½d. (15 centimes); above 15 and up to 30 miles, 2d. (20 centimes); above 30 and up to 75 miles, 3d. (30 centimes); above 75 up to 120 miles, 4½d. (45 centimes); above 120 miles, and up to the greatest possible distance in Switzerland, 6d. (60 centimes).

"Value parcels are taxed generally according to their value, but if their weight gives a higher rate than their value, they are rated by weight.

"A parcel weighing between 1 lb. and 2 lbs., with a value of 200 francs (£8), would cost, from Zurich to Geneva, 6d. The post is answerable for the value of the parcel, which has determined the rate of postage.

"Newspapers and printed matters pay, throughout Switzerland, up to 15 grammes (not quite three-quarters of an ounce), 2 cents. (not quite a farthing); from ¼ oz. to 10 ozs., 5 cents, ½d.; from 10 ozs. to 20 ozs., 10 cents, 1d. These parcels, if above 20 ozs., pay as weight parcels.

"Letters (local rate) pay, up to six English miles, for 10 grammes (not quite half-an-ounce), ½d.; from not quite half-an-ounce to 10 ozs., 1d.

"Letters throughout Switzerland, not quite half an ounce, might pay 1d. if prepaid, 1½d. if not prepaid; from half-an-ounce to 10 ozs., 2d. if prepaid, 3d. if not prepaid.

"Our postage is cheaper and more extended than in the neighbouring countries. Our telegraph costs a franc throughout Switzerland for every twenty words; five words more cost 2½d. Baden, Wirtemberg, Bavaria, have the same telegraph tax, but their wires are not nearly so numerous as ours. I am told that Switzerland has many more telegraph lines and offices than any other country; in fact, we can telegraph to every village, and to the tops of all mountains where any hotels are. Telegraphs are so good and so cheap that everybody uses them—rich and poor—consequently they pay very well. We are now introducing telegraph stamps."

Mr. Rumbold, in his report to the Foreign Office on the Federal finances and expenditure, states that the interests of Switzerland at large have been "admirably served" by the transfer of the Continental post to the central authority under the existing system; the effects of the new postal system exceeded every expectation:—

"The gross receipts of this branch of the public administration, which in 1849 only reached the sum of

4,898,327 francs, had increased in 1861 to 7,112,951 francs, and are reckoned in the budget for this year (1866) at 8,607,500 francs. According to the report of the Federal postal department for 1864 (the report for 1865 has not yet been published), the net receipts amounted to 1,503,302 francs 50 centimes, as against 758,212 francs in 1850. The number of letters increased in the same period from 15,106,117 to 34,325,916; the parcels sent by post from 2,099,368 to 4,813,264; the newspapers sent by post, from 10,601,325 to 25,026,095. I may mention here that the number of newspapers sent in 1864 exceeds, by no less than 1,562,625, that of the newspapers sent in 1863."

MEETINGS FOR THE ENSUING WEEK.

- Mon.....** Society of Arts, 8. Cantor Lecture. Mr. John Hullah, "On Music and Musical Instruments."
London Inst., 7. Mr. G. A. Macfarren, "On the Lyrical Drama."
R. Geographical, 8½. "Last Journey of Dr. Livingstone."
Despatches from Dr. G. E. Seward and Dr. J. Kirk.
British Architects, 8.
Actuaries, 7. Mr. Peter Gray, "On the Construction of Tables by the Method of Differences." Part III.
- Tues ...** Medical and Chirurgical, 8½.
Civil Engineers, 8. Discussion "On Steep Gradients and Sharp Curves;" and (time permitting) Mr. W. A. Brooks, "Memoir on the River Tyne."
Ethnological, 8. 1. Professors Huxley and Busk, "On the Skulls of the Ainos, Chinese, Hottentots, Kaffers, and Burmese." 2. Mr. J. Crawford, "On the supposed Aborigines of India as distinguished from the Civilised Inhabitants." 3. Dr. Hyde Clarke, "On Ancient European Mines."
Royal Inst., 3. Rev. G. Henslow, "On the Practical Study of Botany."
- Wed ...** Society of Arts, 8. Mr. C. F. T. Young, "On Flax, and Improved Machinery for its preparation."
R. Society of Literature, 8½.
Archæological Assoc., 8½.
- THUR ...** Royal, 8½.
Antiquaries, 8½.
Zoological, 8½.
Philosophical Club, 6.
Mathematical, 8.
Royal Inst., 3. Mr. W. Pengelly, "On Geological Evidence in Devonshire of the Antiquity of Man."
- Fri Royal Inst., 8. Prof. Frankland, "On the Water Supply of the Metropolis."**
- Sat Chemical, 8. Annual Meeting.**
Royal Inst., 3. Mr. W. Pengelly, "On Geological Evidence in Devonshire of the Antiquity of Man."

GRANTS OF PROVISIONAL PROTECTION.

- Alphabets and reading, teaching—476—B. Mitford.
Answers to selected questions, instruments for giving—435—J. Parkes.
Axle-shafts and axle-boxes—412—J. G. Stidder and E. Morris.
Beacons—312—Earl of Caithness.
Boot and shoe toe-pieces—416—D. Tensilwood.
Bottle-stopper and key, a self-closing—392—P. D. Collins.
Breech-loading fire-arms and ordnance—468—J. Bishop.
Brushes—508—C. Turner.
Buildings, floors and roofs of—452—H. Y. D. Scott.
Buttons—384—R. T. Thompson.
Candlesticks—531—H. R. Du Pré.
Carbonate of soda and of potash—494—C. Kessler.
Carding engines—290—J. B. Booth.
Carding engines, feeding—428—J. Ferrabee.
Cartridges, central fire—512—J. Syme.
Casks, cleansing—496—T. King.
Chain beaming apparatus—420—J. P. Kerr and W. McGee.
Chairs—501—C. G. Gumpel.
Chimnies, preventing down draught in—444—C. Wenner.
Cricket spikes—490—J. Wareing.
Dining-tables—434—H. Cooper.
Engines, &c., transferring—386—J. Ramsbottom.
Envelopes—524—E. Hely.
Envelopes, &c., securing—491—C. M. Tate.
Fats, &c., boiling—515—W. Barratt.
Fibrous materials, preparing—529—J. Tatham.
Fibrous materials, scutching, &c.—450—E. Brasier.
Fibrous substances, drawing—426—J. Combe.
Fire-arms—326—J. Box.
Fire-arms, breech-loading—392—J. H. Johnson.
Fire-arms, breech-loading—460—A. Albini and F. A. Braendlin.
Fire-arms, breech-loading—410—J. F. Blaud.
Fire-arms, breech-loading—504—I. M. Milbank.
Fire-escapes, portable—572—R. A. Jones and J. C. Hedges.
Fire-places—590—B. Thring.
Foot-rot in sheep, curing—564—M. Woolrich.
Friction matches, packing—414—J. V. Toepken.
Furnaces—354—H. E. Falk.
Furnaces—517—J. A. and J. Hopkinson, jun.
Furnaces—578—B. Sheard.
Gas engines—499—A. Kinder and W. B. Kinsey.
Hammers—440—R. Thwaites, E. H. Carbutt, and J. Sturgeon.
Hard materials, breaking—455—T. Archer, jun.
Iron safes—400—J. Westwood and E. Baillie.
Lamps—404—H. Houfe.
Lamps—406—W. Jones.
Lamps—525—G. Young.
Laths—528—J. L. Sharnan.
Liquids, drawing off—424—P. Duchamp.
Liquids, extracting—531—C. E. Brooman.
Meat, preserving—378—E. Gorges.
Metallic alloys—505—P. A. Munz.

Meters—109—J. Colvill.
Motive engines, regulators for—580—F. A. P. Van deputte.
Motive power—472—E. G. Breyer.
Motive power—486—C. Colwell.
Motive-power engines—422—R. Shaw.
Motive-power engines—474—J. Weems and T. Robertson.
Motive-power engines—498—H. Purnell.
Mowing and reaping—588—G. M. Garrard.
Oxygen, producing—568—W. Clark.
Patent leather, &c.—446—A. A. Fousset.
Peat, treating—512—E. Chapron.
Pen-boxes, &c.—374—F. Leonardt.
Phosphatic minerals, preparing—47—W. Way.
Photographic pictures—20—W. G. Helsby.
Pictures, exhibiting—380—A. G. Grant.
Portfolios, &c.—510—G. Liddingham.

- Pump-roads, counterbalancing—406—W. West and J. Darlington.
Rag engines—482—J. R. Crompton.
Railways, an alarm for the use of—523—E. Funnell.
Railways, calls for—506—B. Billingham, A. Griffiths, and J. Dalley.
Railways, signalling on—519—G. Daws.
Railway trains, electric signals on—488—A. I. L. Gordon.
Sails of annulus—358—W. S. Losh.
Saw frames—478—J. Robinson and J. Smith.
Sewing machines—396—A. V. Newton.
Ships, removing sea-weed, &c., from—484—J. Harrison.
Smooth surfaces, polishing—462—R. Kunstmann.
Soap—492—W. Clark.
Sinning, &c., steel caps—500—W. Deakin and J. B. Johnson.
Stays, &c.—468—S. Osborne.
Stays, &c., a new fabric for—529—A. C. Laury.
Steam boilers—276—W. and D. Flaken.
Steam boilers—376—R. James.
Steam boilers—516—J. Alison.
Steam boilers, &c., fluid safety gauges for—511—J. Marshall.
Steam engines—527—C. Martin.
Steam engines, condensing—538—J. Wild, jun.
Steam engines, regulating—448—A. Benoit.
Steam generators—402—W. E. Gedge.
Steam toys—2901—C. Sutton.
Substances, grinding—566—J. Bellerby, jun.
Tallow cups—507—J. Bates.
Tentering machines—398—W. Clissold.
Textile fabrics, &c., sewing—574—J. H. Johnson.
Threads, preparing—500—C. E. Brooman.
Ticket-holders—412—H. A. Dufrené.
Trap doors, &c., securing—436—E. Stevens.
Vehicles—383—W. Stratford.
Vehicles, wheels for—470—G. Haseltime.
Veneers, cutting—570—A. V. Newton.
Vessels, raising—441—A. Dillon.
Weaving, looms for—430—E. Lord.
Windmills—442—W. H. Harfield.
Windows, &c., securing—432—J. Carter.

INVENTIONS WITH COMPLETE SPECIFICATIONS FILED.

- Bath belts—599—M. J. E. Jullienne.
Leather, hardening, &c.—651—W. H. Towers.
Needle cases—669—J. E. Asselin.
Pianofortes—823—W. E. Gedge.
Scissors or shears—649—B. Snow, jun.
Solutions, preserving—684—H. A. Bonneville.
Steam boilers, feed-water regulators for—514—G. Haseltime.
Steam engines, &c., packing for—513—G. Haseltime.

Journal of the Society of Arts.

FRIDAY, MARCH 29, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

APRIL 3.—The following subject for discussion will be introduced by THOS. HAWKLEY, Esq., M.D. Lond.:—
"How to provide Healthy and Cheap Dwellings for the Working Classes with Financial Success."

CANTOR LECTURES.

A Course of Lectures "On Music and Musical Instruments," by JOHN HULLAH, Esq., is now being delivered as follows:—

LECTURE V.—MONDAY, APRIL 1.

MUSICAL INSTRUMENTS.—Classification.—Wind Instruments—Stringed Instruments—The Plectrum, Hammer, and Bow—Instruments of the Ancients—Mediæval Instruments; their Introduction into the Church.

LECTURE VI.—MONDAY, APRIL 8.

MUSICAL INSTRUMENTS (continued).—Modern Instruments—Chamber and Orchestral—Combination—The Modern Orchestra—Conclusion.

The lectures commence each evening at eight o'clock, and are open to members, each of whom has the privilege of introducing one friend to each lecture.

SUBSCRIPTIONS.

The Christmas subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

The Sub-Committee on Meat met on Friday, the 15th instant. Present—Mr. Harry Chester, in the Chair; Messrs. C. S. Read, M.P., C. Wren Hoskyns, F. Parish, E. Wilson, J. Ware, and J. Ludford White.

Mr. TINDAL, of Clarence River, New South Wales, attended, and in reply to questions from the Chairman and other members of the committee, stated that he was one of a private company of twelve, who had embarked capital in a meat-preserving establishment at the Clarence river, where he resides. The Company kill a large number of cattle annually, and are now sending over the meat preserved in a cooked state in tins, after the well-known process which has been so long in use. Consignments are made to Messrs. McCall and Co., in this country. The Company had already sent two consignments of

about 60,000lbs. and had made arrangements for sending that amount monthly. This is sold in six pound tins, at 7d. per lb. retail for the best parts, and 6d½. per lb. for the inferior parts. It has hitherto been sold principally for shipping purposes. The cattle are in the best condition for killing in the months of April and May. They can kill 10,000 head annually. Mr. Tindal considers that an Australian bullock furnishes more and better meat than a South American bullock. Only the meat is preserved, and the bones are dealt with in other ways. The shank bones are worth from £10 to £15 a ton, and are sent to England; the other bones are ground and used for manure. The ground bones would not pay to send to England, the freight is too high. In reply to questions in reference to this sending of meat to England, Mr. Tindal stated that the process was equally applicable for mutton, but that it would not pay so well commercially to send over mutton. In the first place, the mutton was dearer than beef—the wethers are kept longer before coming to maturity than bullocks—the former being kept seven years, whilst the latter is fit to be killed in four years. Again, as the bones have to be taken out, there is as much labour in taking out the bone of a sheep as of an ox, or nearly so, and the proportionate amount of meat is much larger in the one case than the other. It therefore does not pay so well to send mutton as beef. The cattle in Australia are originally of English breed, and by the purchase of English prize bulls the breed has been brought to a high degree of perfection. Mr. Tindal's company make and export the *Extractum carnis*. The sale is greatly increasing. The company has in their pay a scientific chemist, under whose superintendence the company's business is conducted. The *Extractum carnis* cannot be made profitably from veal, or, indeed, from any young meat; veal meat is very deficient in the materials which form the *Extractum carnis*.

Mr. McCALL, of the firm McCall and Co., Houndsditch, provision merchants, stated, in reply to questions from the committee, that the trade in Australian preserved beef was quite new, and at present the sale was confined to the shipping trade; indeed the article was unknown in the home trade, but it was his intention to place it before the public generally through the ordinary retail channels, and, until this was carried out, his firm were willing to supply a single tin at the above-named prices. Some persons objected to the meat being cooked, and they were now experimenting with a view of bringing in preserved uncooked meat; but, although these experiments were promising, they had not hitherto succeeded in obtaining such a measure of public support as would enable them to embark in that enterprise. With regard to turtle, he stated that the turtle were killed in Jamaica; the calipash and calipee, or lining of the shell, is dried, packed in tin-lined boxes and sent over to this country. The turtle flesh is not sent over. This dried calipash and calipee, when required for use, is soaked for several days, and made into soup with veal stock. The main supply of turtle soup is thus made. Live turtle, no doubt, are sent over here, but a very large number of them are only fit to be killed immediately on their landing, and their calipash and calipee is dried for preservation until wanted for use. Messrs. McCall preserve large quantities of English meat in the same way as that in which the Australian meat is preserved. The bones form 25 per cent. of the carcase; thus a 6lb. tin of meat represents 8lbs. of butchers' meat. He further stated that the heavy beef preserved in this manner at the Deptford Victualling yard must cost the government 11½d. per lb. He could offer Mr. Tindal's Australian beef at 7d. per lb., with a discount of course on the sale of a large quantity.

Lord De L'Isle laid before the Sub-committee on Milk, at one of their Meetings, the following remarks on—

THE SYSTEM OF COW-KEEPING AS PRACTISED IN THE NORTH OF ENGLAND, AS REGARDS THE SUPPLY OF MILK TO THE LABOURING CLASSES. By Mr. STURGESS.

The system of cow-keeping practised by a portion of the agricultural labouring class living in the agricultural villages in the north of England is of old growth, and has now become, to a certain extent, an institution of the district. There can be no doubt in the minds of those who have seen it in operation, that it has tended to the improvement of the position of the industrious and painstaking labourer, enhanced in a material degree his home comforts, given him an interest in the locality, and bound him with a tie of no ordinary character to the occupation he holds; further, it has been the means of retaining in districts many steady, good workmen, who have been of essential service to the farmer located with him in the same parish. This system of cow-keeping, I think, may be considered an elder member of the garden allotment system, for the aim of the latter was, no doubt, to advance further, but in another form, the principle of getting the labourer to settle down, by attaching to his cottage a small plot of garden ground, wherein he could occupy the leisure-hours of himself and children, and thus add to his means for procuring more comforts for his family. Before giving particulars of the system, it would be well first to mention that it necessarily involves some additional expenses to be incurred by the owner, in providing the needful accommodation for cow-keeping, and sub-dividing the land with quick fences or post and rails into small and convenient-shaped holdings; and although this expense at first sight may appear heavy, yet I do not doubt that, with the increased rent generally obtained for the cottage and land over what is paid by the neighbouring tenant-farmer for similar land, the cottager pays interest, in the shape of rent, for the additional accommodation that has to be provided for him under this system. The additional accommodation may be stated simply to consist of a small additional space being required in the cottage for a dairy, say about 8 feet long by about 6 feet wide. The cow-house should be about 12 feet long and 8 feet wide; this would give room for one cow and a calf, or, if the latter was not kept, two cows might be accommodated. The pig-stye cannot be called an addition, it being generally attached to all cottages in agricultural villages. The extra cost, therefore, for dairy-room in house, with cowhouse, would not be more, I estimate, than from £20 to £25, in fact, in many places, the accommodation required is put up at a very trifling expense.

I now beg to add the following particulars in regard to the extent of land occupied with cottages under this system, the amounts of rent paid, with a description of the class of labourer holding those tenancies in the north, and which, I must observe, more particularly refers to the North Riding of Yorkshire:—

Description of Labourer.	Land occupied.			Rent paid for Land and Cottage.		
	A.	R.	P.	£	s.	d.
1. Worked in a brewery....	1	0	36	..	10	10 0
2. General farm labourer ..	5	2	15	..	16	15 0
3. Ditto ditto ..	2	1	22	..	15	10 0
4. Bricklayer ..	3	3	13	..	14	2 0
5. General farm labourer ..	1	1	14	..	6	12 0
6. Ditto ditto ..	1	3	22	..	10	6 0

The houses attached to the above occupations are good, and where the land held exceeded two acres, the tenants had increased accommodation for additional stock keeping. I may also add that, in connection with the above tenancies, the tenants had the opportunity of "gating" out his cow during summer in a gentleman's park adjoining the village, thus giving him an opportunity of cutting his own grass for hay. The cost, I may note, for pasturing a cow from May-day to Michaelmas (20 weeks) varies from 60s. to 80s., according to size of animal.

Particulars of certain Occupations continued, but taken from another part of Riding.

Description of Labourer.	Land occupied.			Rent paid for Land and Cottage.		
	A.	R.	P.	£	s.	d.
1. General farm labourer ..	10	1	21	..	13	10 0
2. Worked on the public roads.....	5	0	2	..	10	19 0
3. Gentleman's servant	5	0	27	..	12	10 0
4. Village blacksmith	4	2	34	..	14	14 0
5. „ carpenter ..	6	1	33	..	21	0 0
6. General farm labourer	8	5 0
7. Ditto ditto ..	8	2	19	pasture	8	5 0
8. Ditto ditto ..	5	2	0	meadow	8	5 0
9. Ditto ditto	8	5 0

The four last occupations had a pasture field allotted among them, containing 8a. 2r. 19p., so they all had an equal number of cows in it. The meadow field 5a. 2r. 0p., was divided by stakes into four portions, so that each knew his own meadow piece for cutting. The first five occupations in the above list had sufficient ground for keeping two or more cows both winter and summer.

Particulars continued, but taken from a different part of the Riding.

Description of Labourer.	Land occupied.			Rent paid for Land and Cottage.		
	A.	R.	P.	£	s.	d.
1. Village carpenter ..	4	0	39	..	12	0 0
2. General farm labourer ..	1	2	22	..	6	0 0
3. Ditto ditto ..	6	2	18	..	9	15 0
4. Ditto ditto ..	4	3	34	..	8	0 0
5. Ditto ditto ..	4	2	0	..	8	0 0
6. Village schoolmaster	3	3	3	..	7	16 0
7. „ smith ..	5	0	28	..	13	14 0
8. General farm labourer ..	3	0	22	..	9	10 0
9. Village shoemaker ..	5	0	9	..	10	0 0

In some of those last-named occupations, where the quantity of land was not sufficient for pasturing a cow during summer, and reserving a portion to cut for hay, the cottager either got a grant to run his cow in the lanes, or, if that was not obtained, he generally got pasturage with a neighbouring tenant-farmer.

In reference to the disposal of the produce of the cow, it may be stated that, as a general rule, it is made into butter, for which in the district there is a steady and regular demand, arising principally from the increase of large manufacturing towns in the Riding. It is, however, not to be understood that no milk from the cows is sold; on the contrary, where any labourer in a village is without a cow he can have a good supply at 1d. per pint. Under those circumstances there is no lack to those desirous of obtaining it. Of the skim milk which is left after the cream is taken off, part is used by the family, and part is sold, the remainder going to help the feeding of one or two pigs.

From a personal knowledge of the system, extending over more than 20 years, I can speak to its beneficial effect in promoting industry, giving greater comfort and many additional luxuries to the labouring man's family, and also as having been the means of promoting socially his own and children's advancement. In many instances I have known that it has helped the labouring man to place one or two of his sons in a useful trade; and as regards the female portion, it has helped, by the duties incident to their position while at home, to prepare them for making useful servants to the farmers and others resident in the district. In respect to any difficulty in obtaining tenants for those small occupations, I can only add, that on a vacancy occurring it is eagerly inquired after, and soon a choice of tenants offers; further, as to punctual discharge half-yearly of the rents, it is satisfactory to state that an arrear rarely, if ever, occurs. I have never known one.

The success which, as shown by the foregoing remarks, attends the cow-keeping system, has only

en attained by the length of time it has been in veneration, as it must be evident to every one who has made inquiry into its working, that a great deal depends upon the management and skill which the labourer's life can bring to bear to the occupation, it being left principally in her hands to manage; otherwise without that skill it could not be expected to succeed. It may also be noticed that the system under consideration is now so far recognised as to the advantages which it has conferred, that there is a regular prize now offered by the local agricultural associations for the best cottager's cow; and in this class at those local gatherings cows of excellent quality are exhibited. The cow clubs are also numerous among them, where, by a small annual payment, the loss of a cow is provided against.

In making a few concluding remarks as to how this cow-keeping system could be applied to the south, I may note, first, as regards the land, that I think the grass lands of the north are better, as well as the herbage; they are also, in the neighbourhood of the villages, divided into small fields, suitable for this class of occupation. I have not found this so in some of the districts south of London. This, however, in itself, need not be a fatal objection to a trial of the system, if other circumstances were favourable. Of course, in the chalky districts, where the grass lands are very poor, the system could not be introduced with any fair prospect of success, for owing to the quantity of artificial food which would have to be purchased to assist to keep a cow in condition on this description of land, the expense of this artificial food would deprive the system of the advantages it is presumed to confer.

Taking, however, the other districts of the south, where the grass land is of fair quality, and where facilities would be given for dividing a few grass fields into suitable occupations for the keep of a cow, there is the practical difficulty yet to be got over, that neither the labourer nor his wife, especially the latter, is qualified by previous experience to undertake the management of cows; further, it is not a system that can be taken up at once, although funds may not be wanting for providing the cows, &c. It is upon the experience of the housewife that so much depends to make the occupation of advantage, aided no doubt by the co-operation and assistance which she receives from her children, who are early instructed in those duties. In my experience of the south, I should say that it is next to impossible to find a female, wife or servant, that can milk, let alone knowing anything about butter-making and other duties attending the successful working of the system. Further, it is far from general that the labouring man knows anything about cows, or is able to milk one, and, therefore, however well the system may be shown to answer in the north, it would not follow, from the circumstances before noted, that if tried it might be equally successful in the south.

The economy of living and the food consumed by the labouring class in the south are very different to the custom in this respect in the north; in the latter more animal food being taken and more milk used, whereas in the former meat does not enter into consumption except to a limited extent, and, in the place of milk, beer or cider is the substitute. The use of the two latter as a part of the domestic economy of the labouring man's household, is, I am afraid, a great inducement to his visiting and being found often at the beer house.

If the system could by any means be introduced, there is no doubt that much good might be derived from it, not only in elevating the position and character of the labouring class, adding greatly to his home comforts, but also further (which I should myself put some stress upon), in the duties which would necessarily be thrown upon the family; these would tend to qualify them for making good and creditable servants, who would thus be more conversant with the duties required of them in many situations they might be called upon to take.

These few suggestions have occurred to me in the consideration of this subject; no doubt more detail could be

entered into if space was available, but I trust the little I have adduced in reference to this matter may be of service in helping to bring into notice a branch of cottage economy which I believe has been and is now doing good service in the north of England.

In reference to the foregoing memorandum, Lord De L'Isle writes:—

The above able and comprehensive remarks of Mr Sturgess, so thoroughly explain the subject, that comment on my part is almost unnecessary.

I would simply observe that the system of cow-keeping in the north of England is one of long standing, the growth of years, and it has tended much to the comfort of the labouring class. Whether such a system could be established, in suitable districts in the south, with fair prospect of success, is a question which requires some consideration.

The principle of allotments has answered well in certain places, in others it has not met with the same amount of success.

The habits of the labourers in the north differ much from those of the south, and in the management of a dairy much depends on the skill, cleanliness, and industry of the wife.

In the north most of the labouring-classes are well acquainted with the management of dairy-stock, but this is not the case in most parts of the south of England, where great difficulty exists in finding either a man or a woman who can even milk properly.

These are some of the difficulties which would attend the introduction of this system; but I cannot help thinking that, from the success it meets with in the north, it is well worthy the attention of landlords, as a means of giving to the labourer a more permanent interest in the soil, and by his own industry and good management adding many comforts to his home. It would also enable him to sell milk in small quantities to those of his own class who now frequently experience great difficulty in obtaining even a limited supply.

CANTOR LECTURES.

"ON MUSIC AND MUSICAL INSTRUMENTS." By JOHN HULLAH, Esq.

LECTURE IV.—MONDAY, MARCH 25.

MUSICAL NOTATION.

Having described the four properties of musical sound—duration, pitch, intensity, and timbre—Mr. Hullah said that the first two of these were incomparably the most important. Duration and pitch (time and tune) are not so much essentials of music as music itself. Without time musical sounds want form; without tune they want life. An efficient musical alphabet must be competent to represent, or convey accurately, duration and pitch. In this respect the alphabet of music will differ from all others; since, with a few partial exceptions, no other attempts to represent anything but sound, and that in a very unprecise manner. Two systems of musical notation have long existed—the one alphabetical, the other express or especial. The former is much the more ancient, the latter has proved incomparably the more convenient. No monuments are extant of the musical notation of the Assyrians, Egyptians, or Hebrews. The Hebrew accents now in use are comparatively modern, but it is believed that something like them was in use in earlier times; and accents, if not exactly numerical notes, are akin to them. Musical notations, borrowed from existing alphabets, have long been used in the East. In these the letters were modified to express duration. This was effected by accessory signs. The notation of the Greeks (also alphabetical) was originally very simple, but in later times it became complex, through the increased number of modes, a separate notation for instruments, and generally a more ornate style of music. The Romans,

always imitating the Greeks in art, used the first fifteen letters of their own alphabet for numerical notes. Special musical notation began with the early middle ages. The public libraries of Europe abound with MSS. of the 8th, 9th, 10th, 11th, and 12th centuries, noted in characters not belonging to any known alphabet. These are of two kinds; one formed of little marks, varying in position, each representing an individual sound; the other of lines fantastically bound together, representing groups of sounds. To these two kinds of musical notation may be traced our own—of the perfection and fitness of which he proposed to speak presently. From the detached signs come the long-breve and semi-breve; and from the contorted lines come our groups of quavers, semi-quavers, &c. This ancient notation is known among musical antiquaries as *neuma* notation—a name first given to it by Du Cange. The derivation of modern notes from neumas is not difficult to trace; but the origin of the latter has been a subject of much controversy. Mr. Hullah then gave an account of the theories on the subject, of Theodore Nisard, Kiesewetter, Fetis, and De Coussemaeker, giving the preference to that of the latter, who derives neuma, and therefore our present notation from the three accents of speech—the acute, grave, and circumflex. The first difficulty in respect to this theory lies in our inexact use of the word *accent*, which was generally confounded with emphasis or stress, a part, but not the whole of accent. Ben Johnson calls accent the “tune of speech,” a definition in accordance with the derivation of the word. Admitting that accent is something more than emphasis, there is nothing unreasonable in the supposition that characters adopted for the purpose of bringing to mind the tune of speech should have been adopted and improved for fixing the more strictly musical tune of song. From the eighth to the twelfth centuries, during which neuma notation was used throughout Western Europe, it underwent many modifications, the general result of which was its eventual transformation into the square notation still in use for plain song. In the earliest extant specimens of neuma notation may be traced indications of the fundamental principle of modern notation, the expression of relative pitch by relative position. But this expression was for a long time very inexact. Notes were frequently misplaced; and even in their proper places they were often difficult of comparison. The idea presented itself to some acute mind, of drawing a horizontal line, the pitch of which, once agreed upon, would determine that of the notes immediately about it. “Il n’est que le premier pas qui coûte,” in arts as in morals. Improvement on this contrivance was easy, all but inevitable. If one line contributed to accuracy, two would be better still; and for some time two lines, distinguished by different coloured inks, were used, an initial letter on each, indicating the notes standing upon it. These were the first clefs. Subsequently a line was inserted between these two; and subsequently again the number of lines was increased to four; this number being in later times greatly increased, and ultimately reduced to the present number, five. The adoption of the stave, by making the places of the notes more easily recognised, soon induced greater accuracy in their forms, certain varieties of which, at very early periods, no doubt indicated different lengths. Like the history of the stave, that of “Time table” might form the subject of many lectures. The very simple proportions of notes to which we are used are the result of ages of experiment. From the end of the 12th century to the end of the 16th, the most extravagant complex means were in use to express even the simplest rhythmical relations; and many rhythmical relations were often anything but simple. Even after much of this intricacy was cleared up, music—even easy music—must have been very hard to read. Till about the beginning of the 17th century stave music was commonly written and printed without bars. The bar was no doubt used as early as the 11th century, but not to divide notes into measures, but into phrases;

in no way answering the purpose of our bar, viz. besides dividing notes into equal quantities, incidentally shows to what notes the principal emphases are due. The word *score* has grown out of the act of drawing down the superposed parts of a composition—the *scoring* the page. Mr. Hullah then traced the great multiplication of the number of forms of notes in new times, and the modifications to which these had been subjected, not merely in form, but even in colour; and showed by what simple contrivances, such as the dot in the triplet, the more intricate contrivances of old times had been replaced. Musical notation had not reached as high a pitch of perfection as could be expected of any human invention. It was understood and accepted too by all who practice the kind of music which it seeks to express—the whole civilized world. The fact, as it should be, that the only universal language was the only universal alphabet, and it might have been expected that all who speak the one would unhesitatingly adopt the other. The fact that a symphony, or a song, composed by a native of France or Germany, was played or sung by an English orchestra, or a Russian chorus, without chance of any serious misunderstanding on the part of the latter, of the intention of the former might be supposed a good *a priori* argument in favour of a means of communion between persons so distant in many ways so unsympathetic. The fact, too, that this means of communion men of all nations had contributed something, and that its settlement had taken at least a thousand years, ought to weigh a little with every body who knew how hard it is to get even half a million of people to settle or agree upon anything. There was continually springing up, however, advocates of new systems of musicography the adoption of which would reduce our musical heir-looms to the level of waste paper, and most existing musical science and skill to the level of those of these advocates; for it is remarkable that no scheme for the reformation of musicography has ever been proposed by any person of acknowledged musical science or skill. Mr. Hullah then proceeded to present in review the principal objections to our present musicography—that it occupies much space; that it is laborious to write; and, above all, that it is difficult to read. That many musical compositions occupy much space is not to be denied; but whether they occupy space disproportionate to the wealth of thought contained in them; to the occupation they give to those who have to interpret them; to the sensations, delightful and elevating, which they cause in those who hear them, are quite other questions. The second objection, that music is extravagantly laborious to write, could only be seriously entertained by people who have never set foot in a great musical library, or opened a great musical catalogue. To the beginner in musical penmanship the art may appear to admit of very slow practice, but experience shows that a fair amount of exercise gives a most dangerous facility of expression, so often turned to account by those who have nothing to express. Mr. Hullah proceeded then to deal with the objection that the present mode of writing music gives unnecessary trouble to those who have to perform it. This he did chiefly by reference to the most elaborate form of music—the full score, wherein was shown the superiority of a pictorial form of expression, such as musicians use, to a mere symbolical form, like any of those used in the mathematical sciences. In reference to the reading of a score, he said that if our present mode of writing music were as complex, as illogical, and as clumsy as its adversaries pretended, the reading of a full score must be the most stupendous operation ever achieved by the human intellect. Putting aside, however, all considerations merely musical, and confining himself to the humblest, though not the least interesting of operations—teaching the elements of singing to young children, he said that the would-be reformers of the stave confounded two very different things—the cultivation of the eye and that of the ear; or else took it

for granted that the former was by far the most difficult operation. So far from this being the case, Mr. Hullah's experience had convinced him that the cultivation of the eye was incomparably more easy than that of the ear; and that a very small part, if any, of the difficulties of teaching singing have any connection whatever with the way in which music ever has been, or ever can be, written. It had been taken for granted that the difficulties inherent to the knowledge of sound arose from the difficulties (whether fancied or real does not matter) connected with the use of the symbols which stand for sound. So far from this being the case, they have nothing whatever to do with them. Any person—any child of common intelligence—can be taught in a few minutes that such a note is four positions or “a fourth” from another; but to teach him to utter at will, or recognise when uttered, a sound a fourth above any given sound (written or not written) is a process that requires, and always will require, a good deal of skill on the part of the teacher, and a good deal of time and application on that of the learner. The lecture was illustrated by a large number of diagrams—examples of ancient and modern notation.

SIXTEENTH ORDINARY MEETING.

Wednesday, March 27th, 1867; PETER GRAHAM, Esq., Member of the Council in the Chair.

The following candidates were proposed for election as members of the Society:—

Cassels, Andrew, Manchester.
Eadie, Robert, Blaydon-on-Tyne.
Mendel, Sam, Manchester.
Pagan, John T., J.P., Oak Lodge, Guildford.
Bydon, Horace James, Pyrland House, Highbury New-park, N.
Tolaunt, John, 152, Tooley-street, E.C.

The following candidates were balloted for, and duly elected members of the Society:—

De Vere, Albert, 86, St. James's-street, S.W.
Ellis, E. S., The Newark, Leicester.
Riwa, V. Cary, Billing-hall, Northampton.
Kirkbank, John, 10, Gray's-inn-square, W.C.
Knowles, John, 42, Moorgate-street, E.C.
Pearse, Joseph Salter, 18, Barnsbury-street, N.
Potter, Edward, Marine-house, Tynemouth.
White, Henry Hopley, Q.C., the Firs, Rectory-grove, Clapham, S.

The Paper read was—

FLAX, AND IMPROVED MACHINERY FOR ITS PREPARATION.

By CHAS. F. T. YOUNG, C.E., Mem. Soc. Engineers, Assoc. I.N.A.

Although the especial object of this paper is to treat of the preparation of flax by machinery, it may not be irrelevant to preface it by some observations on the plant itself; and more particularly on the immense importance, in a commercial and national point of view, of encouraging its growth in this country; inasmuch as it might be considered superfluous to speak of the machinery best adapted to its treatment, unless we could previously show that flax itself is much needed, and that it can be very profitably cultivated.

We need not search further than our Bibles for evidence of its general cultivation by the ancient Egyptians and the Israelites; and as it appears that, amongst the latter, the chief portion of the vestments of their High Priest were comprised of fine linen, it is pretty clear that this manufacture of linen from the flax plant had then long existed, and had probably attained to a high degree

of excellence, even in those very early days. Nor have we yet discovered any material so admirably adapted, in its purity, freshness, and durability, to the comfort and salubrity of the wearer, more especially in warm climates. Its general estimation naturally caused its cultivation to spread through the world as population and civilization increased, for which the nature of the plant afforded great facilities, accommodating itself, as it does, to almost all climates, although exhibiting, in regard to its fibre-producing properties, a marked preference for the more temperate and humid regions. Hence all the countries of Europe have produced this plant, and there is scarcely one in which it may not be found at the present day. In an early stage of our own country's history we find it to have been almost universally grown. Even yet there are those living who recollect that the flax or hemp croft used to be a component part of almost every homestead; the term of “hempland,” still attaching to a certain plot of the farm in some counties, being nearly all that is now left to record the fact.

The importation of cotton into England, in the latter part of the last century, produced a complete revolution in this branch of what might then have been called domestic commerce. With this, gradually, or rather, rapidly, came the wonderful inventions of, and continual improvements in, machinery consequent upon the application of steam power. This necessarily led to the concentration of large manufacturing establishments in those localities which the presence of coal, iron, &c., rendered most suitable for such operations. Cotton, which reaches this country in a condition ready for the spinner's use, had manifestly many advantages over flax, which required much previous manipulation; and the struggles of the latter for a precarious existence, in its simple mode of manufacture, became daily weaker, until at length the primitive spinning wheel—whose cheerful whirr, even within some of our own recollections, was often heard at the cottage-door, supplying a frequent subject for the poet's song and the artist's pencil, and whose gyrations furnished for so many centuries a light and pleasant occupation during the winter evenings to the female inmates of the farm-house, contributing in no trifling degree to the more comfortable support of the family—came to be for ever withdrawn, and the spinning of flax, transferred, at last, from the cottage to the factory, is now carried on almost exclusively in a few of the large towns, such as Leeds, Belfast, Dundee, Manchester, &c. In Ireland, indeed, the struggle has lasted longer, inasmuch as the introduction of cotton manufactures has been by no means so rapid or so successful there as on this side the Channel, and the hand-spinning and weaving of flax has had a somewhat longer existence, but the recent introduction of the power loom for linen weaving can scarcely fail ere long to extinguish the last remnant of the primitive mode of manufacture, and to concentrate the almost entire trade in the neighbourhood of populous towns.

But, although the overwhelming monopoly of cotton has thus conduced, during the present century, to so extraordinary a change in the character of the flax trade, and tended to diminish the consumption of linen, it has by no means annihilated it, while the recent lamentable disruption in the American states, whereby the supply of their valuable cotton has been so enormously diminished, has given a considerable and probably a permanent impulse to our linen manufacture.

Both the spinning and weaving of flax has been carried to much greater perfection of late years by improved machinery; and, if the production of linen goods has not increased so much as might have been expected, the cause is to be traced rather to the deficient supply of the raw material than to the want of demand for the manufactured article.

The cultivation of flax, then, has, for this and many other reasons, strong claims on our consideration. Nevertheless, we continue to allow ourselves to be dependent upon foreign importations for upwards of one-

half of our supply, receiving annually from 60 to 80,000 tons of flax, chiefly from the northern ports of Europe, which could be as well or better grown in our own country, and for this supply we are, of course, dependent upon the continuance of our friendly relations with Russia and Prussia, any disturbance of which would place our flax spinners in the same disastrous position as that recently occupied by our cotton manufacturers.

Surely, then, there is reason in the wish that a better supply of flax could be provided for our spinners from the lands of our own country, and in the idea that the present is a desirable moment for the consideration of so truly national and important a subject; for, though the energy of the American planters is great, it can hardly be expected that, for many years to come, the Southern States can sufficiently recover from the fearful shock they have received, to be able to supply us with anything like the quantity of cotton we received from them previous to their civil war; or that we shall be able to procure it, of that peculiarly useful quality, from other parts of the world; the value of linen, therefore, as a necessary article of household use, must, in all probability, continue to be permanently enhanced.

Let it not, however, be supposed that the importance of this subject arises from the circumstance of the diminished supply of cotton. The scarcity of flax, and the great want of it by the spinners, were acknowledged facts long before the commencement of the American outbreak. Frequent meetings had been held, associations formed, and Government appealed to, with a view to encourage the growth of the flax plant—for fibre—in India, without, however, any successful result; for, indeed, neither in India nor in the American states, nor Canada—where also the subject was brought forward—have they climates half so well adapted as our own to the growth of this plant, so far as fibre is concerned, although, as regards seed it is successfully and extensively produced in India and other places. Still, it must be admitted that the results of the American war have given increased stimulus to the trade, and clothed the subject with additional interest.

In attempting to enumerate some of the advantages of flax cultivation, it may be observed that one very interesting and encouraging feature is, that it forms a strong connecting link between our agricultural and manufacturing interests. This advantage it, indeed, shares with wool, and at least equally deserves the national patronage and support, for what commerce can be so generally desirable for us as that which provides profitable employment both for our farmers and our manufacturers—draws them together by bonds of mutual interest—increases our national capital, and circulates it at home among our own people? We at present send abroad some six millions sterling every year in payment for foreign flax, and seed, &c.; and with this foreign aid our flax-spinners, for many years past, have not had anything like the supply they need, even for their present limited works; but were the growth of flax encouraged as it ought to be, there would be no difficulty in producing it in our own country, to the extent in monetary value of fourteen or fifteen millions, or more, if needed, without any disturbance of the usual agricultural course.

It is not easy to estimate all the advantages which would thus accrue to our country, in an agricultural, manufacturing, and commercial point of view.

Our climate, again, is singularly suited to its growth. Moisture is evidently essential to the healthy production of its fibre. Hence it flourishes so well in Ireland; and this is no slight recommendation to a crop in a climate so humid as ours; indeed it seems a point peculiarly commending itself to the consideration of agriculturists, who may thus compensate themselves for a failing crop of wheat or barley by an abundant one of flax.

The short space of time for which it occupies the land must also be in its favour; being sown in April, it may frequently be gathered in June. It is very true that

flax demands care in the preparation of the soil, care in the selection of seed, care in the clearance from weeds; yet these ought rather to be classed among its recommendations than its drawbacks, as such care, which almost insures a profitable crop, results also in permanent benefit to the land.

As regards the actual return made by a flax crop, the farmer, it is well understood amongst those who have been accustomed to grow it, that the entire expenses of preparing the land, sowing, and gathering, including rent, &c., ought not to exceed £10 per acre, while the average produce of the straw and the seed may be fairly estimated at £15. Much more than this is frequently obtained; and, of course, from unpropitious seasons, inferior seed, or injudicious management, the result will sometimes be less. In Ireland far more than this is realized by the small farmers, who set their small quantities of flax themselves, and carry their fibre direct to the spinners; but this is a course by no means suited to the English farmer, whose interest it is to sell his crop at once to those who at their retteries prepare the flax for the spinner's use.

Of the value of the seed for the farmer's own use, independently of its worth as a product for sale, it would seem to be difficult to say too much, though here some care is requisite in its administration, whether in the fattening of bullocks, calves, &c., or as an element in the food of horses, or as an aid in carrying leaf-seed through the winter, or as nourishment for ewes in the lambing season, and in all these cases returning so valuable manure to the land; but so much has been said on this subject by Mr. Warner and other practical writers, that it would be superfluous to go into further details.

Having said thus much on the advantages of this crop, it may be well to touch upon the objections which have been sometimes advanced against it. These are chiefly limited to two, viz., its supposed exhaustion of the soil, and its interference with the harvesting of other crops. The former objection has indeed been often made: it is as old as the days of Virgil; and it is quite possible that in the then state of agricultural science, there might be reason for the charge of its "burning" or exhausting the land. This was the natural result in our own country previous to the introduction of the system of rotation of crops, and of restoring to the land, by natural and artificial manures, those inorganic substances which the plants had extracted from it. Flax and hemp were both grown formerly as articles of domestic necessity, without reference to the nature of the soil, and with little or no aid from manure, the small stock of which was of course reserved for the grain or food crops. It is not unnatural, therefore, that a crop thus grown constantly on the same land should have come to be looked upon as exhausting, but it is now well-known that, where attention is paid to the suitable nature of the land, and due care bestowed on its treatment, flax is, in proportion to its value as a crop, less exhausting to the land than several others which are regularly grown. Experienced farmers admit that, on suitable land, it creates no undue impoverishment, while it leaves the soil in a peculiarly good condition for the succeeding crop. Nay, it has been grown (although such a course is by no means recommended) on the same land each alternate year for eight or ten years, without producing any symptom of unhealthy exhaustion, the grower having, in fact, almost every year carried away the price for the best crop of flax grown in that particular neighbourhood.

It would perhaps be an interesting point to attempt to ascertain how much more a plant of such rapid growth as flax owes to water and to atmosphere than it does to the soil in which it grows; and surely there is nothing in the character of its roots or in the quantity of its seed to demand any unusual degree of absorption from the land, although it may possibly extract some properties which, if we could have our entire will, we might wish

to retain for a subsequent crop; but even in such case no injury can accrue, as, from the small quantity of land which it is desirable to appropriate annually to flax, viz., one-twentieth part only of the arable portion of a farm, so many years would elapse before the crop returned to the same plot, that any idea of injury from exhaustion is utterly out of the question.

The objection of its interfering with other harvesting operations, will not, as a general rule, be valid, under proper management. If the land be in good heart, the seed of the right kind, and sown before the middle of April, it will usually be ready for pulling about ten days before the general harvest. Flax from Dutch seed is indeed of slower growth than that from Riga seed, and has often been the cause of this annoyance, having been frequently used on account of its larger yield of seed. It should, however, be carefully avoided, not only on account of its more tardy maturity, but because the fibre extracted from it is comparatively worthless. Again, if the quantity grown be restricted to the proportion above stated, this is of itself almost a sufficient security against any inconvenient interference with other harvest work.

Here, then, it may possibly be asked—If the growth of flax be so desirable for the linen manufacturers, and so remunerative to the growers, how comes it that so little is produced in England?

Several reasons may be given:—

1st. The impression entertained that it exhausted the soil, and that, being pulled up by the roots, it left nothing on the farm in the shape of either stubble or straw, led to the introduction of a clause in the old leases prohibiting its growth; and although this prejudice may be said to have all but passed away, there are, even yet, some few landlords so strongly wedded to all the systems of their forefathers, without troubling themselves to ascertain their origin, or to weigh their merits, or to reflect upon their consequences, as still to continue this impolitic prohibition.

2nd. The remunerative price of wheat and of live stock in past years, caused farmers to be little inclined to experiment upon a plant of which the present generation knew little, except that it had almost ceased to be grown; and that, therefore, even where it was not prohibited, there were, probably, sufficient reasons, without troubling themselves to analyse them, why they should not attempt to reintroduce it. The present times, however, seem to militate against these easy-going conclusions. The increase of railways in the great corn-growing countries of the Continent is greatly facilitating the importation of both wheat and cattle into England, so that corn, except it be, as in the past year, of almost universal extension, will scarcely now hold out its former consolation of enhanced price. Wheat, therefore, no longer holds its former high position in the farmer's estimation; and the cultivation of so remunerative a crop as flax, though grown to a less extent, would be found a most important addition at the year's end, to his sources of income.

3rdly. And this is perhaps the most cogent reason—the want of a market for the flax when grown. There would be no wisdom in a farmer growing flax unless he had a ready means of disposing of his flax straw as well as of his flax seed. In Ireland, as previously mentioned, the holdings being generally very small, the farmer steeps and dresses his little bit of straw for the spinner by the manual labour of his own family and where the growth is larger he can carry it probably to a not far distant scutch mill, of which there are a good many hundreds spread over the country. In England a farmer generally holds as much land as he can manage; and to fetter himself with the intricate operations of steeping, drying, rolling, and cleaning his flax, on any considerable scale, would be not only very difficult and irksome, but probably from want of the necessary skill and care in the various operations, very unprofitable also. Sufficient for him is the growing and selling it at a remunerative

price. It is therefore absolutely necessary, as a concomitant to the growth of flax, that retteries for cleaning it should be established in the various parts of the country where it is produced, on a scale sufficient to be able to purchase the flax grown within a radius of about 10 miles, this being about as far as it would be desirable to cart it. Wherever such retteries have been established and prudently conducted, they have given very profitable results, and have conferred great benefit upon the agriculturalists of the neighbouring districts by purchasing their flax, and thus encouraging its cultivation; and it is clear that the subject only requires to be better and more generally understood, to lead to a much increased development of this very interesting branch of trade. It is true that in cases where such works have been undertaken by persons without experience, without the necessary machinery, disappointment and failure have resulted; but there is perhaps no branch of trade which holds out a greater assurance of profitable return at the present moment than a flax rettery judiciously conducted upon well-arranged principles, and furnished with the machinery best adapted to the purpose of thoroughly and economically preparing the flax fibre for the spinner's use.

And this brings us to the point which we should probably have reached sooner, had it not seemed reasonable that, before treating of the machinery best suited for the preparation of the flax we should endeavour to establish the position that a greatly increased production is really needed by the spinner, and that it would be very remunerative to the grower, as well as a source of much good to the public at large.

It may seem singular, at first sight, that more rapid progress has not been made in the successful adaptation of machinery to this object; there is, however, a very peculiar nature, subtlety, and delicacy, about the flax fibre, which renders its judicious treatment a matter of no ordinary nicety and of no little study, and which demands the greatest care in every stage of its manipulation. There has indeed been no lack of machines introduced for this purpose; but, up to the present time, the result of most of them has been very unsatisfactory.

Although it is generally known that the thread from which linen goods are made is obtained from the flax plant, it is believed that a very small proportion of the inhabitants of England ever saw flax growing, and that a still smaller proportion have any clear idea by what processes it is prepared for the manufacturer. It may indeed be quite unnecessary here to enter into explanations of this nature; yet the remarks upon the machines themselves would scarcely be intelligible, unless preceded by some account of the work they have to perform.

These processes then, after the plant has been pulled up by the roots, and allowed to dry in the field, are as follows:—viz., seeding, steeping, rolling, drying, stacking, breaking, scutching, and sorting.

1. The first process, that of taking the seed from the plant, is effected by holding the root ends of the sheaf in the hands, and whipping the seed ends a few times quickly between two iron rollers, so fixed that one end of the roller remains open for the free passage of the straw, and set close enough to each other to crush the bolls and allow the seed to fall out without doing any injury to the seed itself. This is a very simple and useful machine, and a great improvement on the previous methods of thrashing or rippling.

2. Then comes the steeping or retting process, still carried on, in some places, in sluggish streams, and in others in pits formed by the aid of streams. By this means however, flax can only be steeped in the warmer months of the year, and even then the variations of temperature render it a very uncertain and tedious operation, occupying from ten to twenty days, according to the state of the weather, and often very imperfectly performed. The object of steeping is to produce such a degree of incipient fermentation, as may soften and remove the glutinous matter, and facilitate, in the sub-

sequent processes, the separation of the fibre from the woody portion of the plant, guarding at the same time against proceeding so far in this operation as to injure the nature and strength of the fibre. This, on a manufacturing scale, is done by means of large vats, in which the water is maintained at one uniform moderate temperature at all seasons, and the process, though requiring watchfulness and care, is accomplished without any uncertainty, and with an immense saving of time.

3. As soon as the straw is sufficiently, and not more than sufficiently steeped—a point of the greatest importance, as on it rests, to a great extent, the ultimate value of the flax—instead of being carried at once to the drying ground, the sheaves are opened, and passed through a machine having several pairs of heavily weighted rollers, with a copious shower of water, falling upon them in their passage through it. By this washing and pressure a large quantity of green glutinous matter is extracted, the release of the fibre from the epidermis and from the stem facilitated, and the fibre much improved in colour and quality. For this washing and rolling process obligations would seem to be due both to Mr. Watt and to Mr. Pownall.

4. The next process (drying) must be atmospheric. Every rapid mode of artificial drying has been found prejudicial to the strength of the fibre; and any lengthened process, by steam or otherwise, would, even were it practicable, involve the necessity of too great an extent of covered space. Spreading on the fields and turning is the usual mode; but the use of horizontal wires, at 18 or 20 inches from the ground, supporting the flax, with its root ends only resting on the ground, insures a great saving both of time and space.

6. When dried the straw should be carefully tied up in sheaves and stacked, and it is desirable that it should so remain for two or three months. It seems thus to recover its nature, and to acquire a mellowness and quality which enhances its value, and also renders it easier to clean.

6. Then comes the separation of the fibre from the woody part, as a preparation for which the flax is passed through what is called a breaking machine, having several pairs of fluted rollers. The intention of these is to crush and break the stem into small portions, and so loosen it from the fibre, that the next process—the scutching, or actual removal of all the woody part—may be comparatively easy; but in this very essential point—a point on which the successful treatment of flax would seem to depend—these breaking machines hitherto appear to have signally failed, and it is more than probable that it is from the want of a better principle at this particular point of the work that many have been deterred from entering upon this really interesting occupation, and that thus the cultivation of flax has been indirectly discouraged.

It must be premised that the essential principle in cleaning flax is to do it without injury to, and without waste of, the fibre. Now, every process of scutching, as the term implies, is by striking the flax; and it is very difficult indeed to give a blow of any kind to this fibre without either breaking some portion of it, and thus converting it into tow, or, if not actually breaking it, so chafing and weakening it as sensibly to diminish its value. Hence the introduction of the breaking machine. Its object was good, but the inventors have failed to accomplish their intentions. It should have absolutely removed a large portion of the shive, or woody matter, and have so broken and loosened the remainder that in the subsequent scutching there would be very little to do, for it must be borne in mind that it is not in the breaking, but in the scutching, that the tow is made. The former, therefore, should have done nearly all the work, merely leaving it to the latter to give the finishing stroke, but in this it has substantially failed. The action of the breaking machines in general use simply flattens, softens, and bruises the woody stem, but it does not remove it. The scutcher, therefore, still has this to do,

and in doing it, whether making use of the Irish method or any other mode, he contrives—not from any fault of his, but from the nature of the machine he uses—to convert so much of the fibre into tow, or to leave so much of it adhering to the broken straw, that the same yield of finished fibre from a ton of green straw is generally calculated at about one-eighth part, i.e. that it requires about eight tons of green or unretted straw to produce one ton of flax fibre.

Now the natural yield of fibre from the stalk of a flax plant is about 1 in 4½; in other words, if it were possible to preserve every particle of fibre, without to lose whatever in the process of cleaning, it would require about 4½ tons of green flax straw to produce a ton of finished fibre.

Surely, then, there exists here a wide margin for improvement. It would be an unnecessary trespass on your time to attempt to enumerate the various machines with their numerous and ingenious contrivances, to accomplish this seemingly easy, but in reality delicate and difficult operation of cleaning flax. Some have been too costly, others too complicated, others too severe in their action, all too limited in their yield, and all have failed to demonstrate the fundamental principle, that the separation of the woody portion from the fibre must be made while the flax is retained in such a position in the machine as not to admit of the possibility of any considerable portion of tow being torn from it.

Now, this most desirable consummation has at last been achieved; and it is to this striking and most important improvement that your especial attention is now requested.

The breaking machine, a model of which is on the table before you, has been constructed by Mr. Bramwell, a practical engineer, who has had a large experience in flax machinery, and whose sagacity and reflection led him to the conclusion that the scutcher was a most wasteful machine as hitherto applied, and that the act of separating the fibre from the shive must be made, if not altogether, accomplished by the breaker, which makes no tow, and not by the scutcher, which makes a great deal.

The machine, as you will observe in Fig. 1, consists

FIG. 1.

one large fluted cylinder or roller, A, on which work four small rollers, B, B, B, B, also fluted, resembling somewhat in this respect the construction of the cotton-carding engine. The object of these rollers, like that in all other breaking machines, is to crush and break the woody part; but in order to accomplish this much more effectually than any other has succeeded in doing, a reverse motion, shorter in duration than that of the forward motion, is added, so that the gradations are, in fact, a long forward motion and a shorter reverse motion, a second forward motion and a second reverse, and a third forward motion, 'whirl' the ends of the flax on to receive the ac-

on of four small beaters fixed upon a horizontal axis, which, revolving continuously in one direction, thus obtain a double relative action on the flax during the time that it is drawn backwards and forwards by the compound action of the rollers.

The principle upon which this reciprocating motion is given is to be found in the natural movement employed by the human hands in rubbing out the husk from any other matter by which it is surrounded, or which it surrounds; thus, in rubbing out corn from the ruff by hand, you naturally give a reciprocating motion to the hands, and in breaking flax straw from the shive," exactly the same movement is almost involuntarily given which is imitated in the present machine.

Thus, to a great extent, the combined action of a reaker and a scutcher is comprised in this very ingenious machine, and so happily that, while a very great proportion (about three-fourths) of the shive is actually removed from the flax, and the remainder is loosened as to be very easily cleared away in the subsequent process, the cleaning action performed by the beaters is effected while the flax is being held in such a position by the rollers as to prevent the formation of any appreciable quantity of tow, and the dust of the scutching mill, which is so prejudicial to health, and so annoying on the present system, is entirely done away with by the use of this machine.

There are other merits in the construction of the machine which can scarcely be represented by the model, the object being to make the working as smooth and true as possible, with the smallest possible amount of power, which does not exceed that of one horse; while the quantity of flax straw which the machine has been tested to operate upon in the day of ten hours, attended by three boys or girls, is about 80 stones of 14lb.

In speaking of the results of this machine, it may be stated that it has been now at work for many months, during which it has been brought to its present state of efficiency, and that there has therefore been ample time to judge of its practical utility.

The average of the trials made from straw purchased in the dried or retted state, is as follows:—

100 lbs. retted straw yields of scutched flax	25.60
It also yields of long tow 7 lbs. = 39 per cent. of flax	2.72
And of short tow 3 lbs. = 26 per cent. of flax	.78
	29.

Now 100 lbs. of retted straw represents about 150 lbs. of green straw, about one-third of the weight being lost in steeping and drying. Therefore, a yield of 29 lbs. flax from 150 lbs. green straw equals one ton of flax from 5½ tons of straw, instead of the general average of one ton of flax from 8 tons of straw, making a difference of 2½ tons of straw in every ton of finished flax. But supposing we allow a large discount for too favourable experiments on cwts. as compared with actual trade results when working by tons, and, instead of calling the yield one ton of flax from 5½ tons of straw, we call it one ton of flax from six tons of straw, we have still a saving of two tons of straw in every eight, or 25 per cent.

It must also be borne in mind that the saving of one-fourth part of the flax straw would not be the only advantage, but the labour also on a fourth-part less quantity of the raw material, which on so bulky an article is very great.

The machine, however, which has been just described, it must be remembered, does not profess to be a scutching, but a breaking machine, although it does, in fact, possess, to a very considerable extent, the attributes also of a scutcher. Its inventor has, therefore, after a thorough examination of the various machines, now, and at former periods, in use, for this last operation of

scutching, constructed a machine (Fig. 2) which seems to be all that need be desired to complete the process.

Fig. 2.

One feature in this scutching machine is the construction of the stock, which is so hinged and balanced that, by an almost involuntary action on the part of the operator, the amount of blow given to the flax under operation, can be perfectly regulated, and thus all loss from undue severity, entirely obviated. It has also the following great improvement attached to it.

It has already been stated that all scutching machines must necessarily make some amount of tow. To this machine, then, has been connected a contrivance (shown at the end of the machine) for at once catching the tow, freeing it from the adhering "shive," and thus delivering at the same time, but from opposite sides of the machine, the flax and the tow—both cleaned.

One other very important advantage of the combined use of these two machines must not be lost sight of. The present general mode of scutching flax by means of the "Irish stock" involves the necessity of employing skilled labour, and the workman who with this machine turns off his three or four stones of flax daily is in the receipt of some 20s. or 22s. per week, the result being that, by this process, the cost of scutching is from 12d. to 14d. per stone; whereas, by the use of these two machines of Mr. Brasier, worked by youthful and unskilled hands, the cost per stone would not exceed 4d. to 5d., independently of the great saving of fibre already alluded to. Touching the last process—"sorting the flax for market"—as no machinery is required, no special notice seems to be needed.

Briefly to recapitulate, then, the advantages to be obtained by the use of these machines, we have:—

1st. The saving of 2 tons in every 8, in the cost of flax straw.

2nd. The saving of the labour on these 2 tons.

3rd. The saving of 7d. to 8d. per stone in the breaking and scutching.

4th. The employment, in this last process, of unskilled, instead of skilled labour, the importance of which manufacturers at least will be at no loss to appreciate.

In conclusion, the author would remark that the foregoing observations have been approved by one who has had a considerable practical experience in the preparation of flax, though not now engaged in it, and who has, moreover, no pecuniary interest whatever in connexion with the machines; but who, having suffered from the imperfections of those hitherto in use, and having satisfied himself, by personal inspection, of the advantages of those which have now been but imperfectly described, is well able to give an opinion; he therefore considers it but right to give this public testimony in favour of an invention which he believes calculated to confer very important benefits upon an exceedingly interesting, though hitherto too little appreciated branch of British agriculture and British commerce.

DISCUSSION.

Mr. BOTLY said he should be happy to learn that the machines, of which an explanation had been given in the paper, would be likely to supersede the very primitive methods in which the produce was formerly treated by the labouring population who grew it in small quantities. He quite agreed with the author of the paper as to the desirability of encouraging the growth of flax in the United Kingdom, and especially in Ireland, but he hoped Mr. Young did not mean to imply that the encouragement was to come from the Government. For his own part he was entirely opposed to Government assistance of any kind in such matters.

Mr. B. FOTHERGILL (responding to the invitation of the Chairman) said he had not intended to take part in this discussion, but he would state what his experience had been in connexion with machinery of this description. About the year 1834-5, when he was connected with the firm of Messrs. Sharp, Roberts, and Co., of Manchester, he constructed one of the earliest scutching machines invented by Mr. Gerrard, a remarkably ingenious man, who derived his ideas of what was required in these machines from observing his wife combing her hair. Observing that if the comb were introduced into the hair near the roots, entanglement ensued, and there was a tendency to tear the hair, but that if introduced near the ends, and gradually carried higher up, no such entanglement took place, it occurred to him that machinery for the combing of flax should be made to operate upon the same principle. The invention of Mr. Gerrard proved very successful, but unfortunately the machine possessed the fault to which reference had been made in the paper, namely, that in this operation, the fibre was broken to a considerable extent, and a great quantity of tow was produced. After that another machine was invented, which was shown at work in the Exhibition of 1851, and patented by Mr. Plummer, of Newcastle-on-Tyne. That was an excellent machine and a great improvement upon all contrivances with which he was acquainted up to that time; but as he (Mr. Fothergill) had now left Manchester for several years, he had got out of the sphere of the flax, cotton, and wool trades, and he had not followed up the history of invention in connection with those industries. He might mention that his father started the first flax mill in Darlington before the commencement of the present century, and with the assistance of his (Mr. Fothergill's) two brothers, machinery for the preparation of the fibre was set to work. At that period they had a contrivance, something analogous to the second machine described by Mr. Young, for operating upon the flax. Still there were the defects with regard to the breaking of the fibre, to which reference had been made, and from that time to the present these defects had more or less existed in all the flax machinery that had been introduced. He, however, thought the combination of the fluted cylinder having fluted rollers, as in the first machine described by Mr. Young, with a reversing action, must be ranked amongst the best contrivances in respect of machinery of this description. The only doubt he had with regard to the machine now before them was whether or not there was a tendency to carry over some of the loose fibre, and thus cause entanglement and waste. If this did not happen he congratulated the inventor on having produced a contrivance which, in his (Mr. Fothergill's) opinion, would well answer the purpose. With regard to the second description of machine, he thought that was somewhat of the character of a modification of the Oldham "willow;" but there was a point in connection with it on which he would ask a question, viz., whether the tow which came from the flax was carried forward and delivered at the other end of the machine in a confused mass of long and short together. If so, he thought the introduction of a second cylinder, to separate the long from the short lengths, as in the carding machine, would prove an advantageous addition.

Mr. COMBES said he was at present constructing a flax-breaking machine, under the patent of Mr. J. E. Dickson, but it differed from that on the table, inasmuch as it had a horizontal reciprocating action; and he considered it a far superior machine to that described by Mr. Young. There was in the machine he had alluded to, a table, constructed like a gridiron, with open bars. The cylinders were four in number, and each cylinder was placed on a separate axis, furnished with pressure springs, so that it could act upon four different strands of flax at the same time. All the straw fell through the gridiron; and he could state, from his own knowledge, that a machine of this kind, 12 ft. long, did not make a point of tow per day. The flax was passed gradually along the table, and every portion of the straw was exposed to different pressures, produced by rollers of different pitches, till every part of the woody substance was broken out, while the fibre remained entirely unbroken. He had not tested the actual quality of work done by this machine, but his impression was, that as two persons could be employed in feeding at each end of the machine, it would be capable of doing double the quantity of work which the machine before them could do.

Mr. CRISWELL said that the machine before them appeared to him to be a combination of the American softener with the ordinary flax-breaker. It was impossible to get a good preparation of the fibre if proper attention was paid to the retting; and in some parts of Yorkshire there were pits on common lands in which the people had access for that purpose; but when the steeping was done at the proper time the fibre became weak and a great quantity of tow was made.

Mr. JOHNSON WILSON said, having acted as consulting engineer to the member for Fifeshire for several years during which time he had erected and managed the works for the manufacture of flax straw, consuming the produce of about 800 acres of land, and producing about 3,000 tons of flax per annum, he might be permitted to offer a few remarks on this subject. He had found it difficult in getting farmers to grow flax; in fact, none of them liked that crop very much. The yield of the crop was very fairly stated by Mr. Young, the average being from £14 to £16 per imperial acre. Sometimes it might be as low as £10; at others it was as high as £18 and £20 per acre, when grown on suitable soil. There was, in the case to which he referred, an excellent market for the seed to the linseed crushers, who readily purchased at a certain price per bushel all the seed that could be produced. It was the seed which extracted the most from the soil; the fibre really took almost nothing, but if the farmers used the linseed cake for their cattle, a great portion of it was returned to the soil in the shape of manure. The straw was often brought from great distances than ten miles; frequently 20 and even 30 miles; in the latter case by railway. Improvement in the steeping had been introduced which increased the value of the flax very much. This operation was performed in a large vat house, and the fermentation of the straw was promoted by the introduction of a small running stream of warm water, in imitation of the Courtall system, and this was found to increase the value of the flax very much, as it washed away the greater portion of the gum as well as promoted fermentation. Flax manufactured at these works had been sold at £130 per ton. As had been remarked by the author of the paper, the scutching had always been the great difficulty in the manipulation of flax, and he believed that had been the principal barrier to the extension of its cultivation. He had brought with him a return of the average results of several years' working, which would be found to be as follows:—

	Cost.	£	s	d
10 tons of straw, at £3 10s.....		35	0	0
Stacking		1	0	0
Seeding		2	10	0
Steeping and drying, seven tons		1	15	0

	£	s.	d.
scutching	8	10	0
ting and baling.....	1	6	0
	50	0	0
YIELD.			
bushels of seed, at 5s.	12	10	0
bushels of chaff, at 3d.	2	10	0
ton of flax	60	0	0
ree cwt. of tow, at 5s.	0	15	0
	75	15	0
as cost as above	50	0	0
rice, fuel, repairs, mill stores, &c.	4	0	0
	54	0	0
For interest and profit	21	15	0

considered this to be a fair profit upon the manufacture, and he was of opinion that it was a trade which ought to be extended in this country. If the Government offered a prize of £1,000 for a perfect scutching machine, the advantages, especially to Ireland, would be very great, and would be well worth the money; and, I thought, if landowners saw their way to the manufacture being easily and successfully conducted, it was a step so suitable to this climate that it would become very extensively cultivated.

Mr. FOTHERGILL suggested that an improvement could be effected in the machine now before them if the rollers, instead of being fluted straight across, were rooved in a spiral form, as he thought this would tend to break off the shive in shorter lengths, and the shorter they were the better.

Mr. D. ROBERTSON BLAINE said, with regard to the agricultural part of the question, he understood from the paper that the cost of producing flax to the farmer was something like £10 per acre, but it did not seem to be clear what was really the profit to the farmer per acre. He apprehended that the success of the crop depended very much upon its being grown on a soil suitable for it. From all they had heard there could be no doubt that our climate was well adapted for its cultivation. A good deal of flax, he believed, was produced in the east of Italy, where the soil was light, and there was a good deal of water; and travelling in those parts one saw the ditches filled with flax, steeping in the rough mode adopted there. He entirely agreed in the opinion expressed as to the extreme desirability of promoting the extension of the cultivation of flax in this country; but it came in the end to the question of the amount of profit at which it could be carried on in comparison with the ordinary grain and root crops.

Mr. JOHNSON WILSON thought Mr. Young had rather overstated the cost of production at £10 per acre. He thought it was under that, including rent, so that there was a profit to the grower of between £4 and £5 per acre. The best quality of flax was that grown on a loose soil, with a clay bottom, the woody portion of the straw being very thin. When grown on a light gravelly soil the reed was strong, and the fibre light and deficient in quality, and a great deal of seed was produced. The flax cultivation in Fifeshire received a check during the period of the Russian war, owing to the high price of wheat, but it had been again taken up there.

Mr. G. B. GALLOWAY spoke in favour of the more extended cultivation of flax, a produce which had so important a bearing upon the commercial interests of the country. He did not agree with the first speaker in his condemnation of Government assistance and encouragement of inventions. In his opinion, if more assistance had been given to inventors this country would have been even greater and richer than it was now.

Mr. WOOD (responding to the Chairman's invitation) said not being a flax manufacturer, and having no special knowledge on this subject, he could not add anything upon it. With respect to what had just been said on the question of Government patronage of inventions, he

might say he had been an inventor for 30 years, but he repudiated wholly any government patronage. Inventors should be content to stand or fall by the merits of their inventions. All he asked was that the Government should let them alone.

Mr. CAMPIN, on the subject of government patronage to inventors, said it seemed to him, however undesirable such a patronage might be in a general point of view, yet in matters of great national importance they were not without instances of good results having accrued from such a course.

Mr. BISHOP remarked that when travelling in Italy he observed that in spots where sunken lakes existed in extinct volcanoes, the people chose that water in preference to any other for steeping the flax in, and from inquiries he made he found that that preference was owing to the benefit which the flax appeared to receive from the chemical ingredients with which the water was charged.

Mr. JOHNSON WILSON said everything which tended to keep the water sweet during the process of fermentation was beneficial to the flax.

Mr. HANCOCK said, in addition to the question that had been raised as to the average profit realised by the produce of flax, there was another question, which he thought had an important bearing upon the case—viz., whether flax must not be regarded as an uncertain crop. He recollected, when travelling in the north of Ireland, that great anxiety was felt as to what the produce of the next flax crop would be; and he believed the difference between the yield of one year and that of another was very considerable.

The CHAIRMAN begged leave to propose a vote of thanks to Mr. Young for having brought this subject before them, and for the able manner in which he had dealt with it. No doubt it was a question very important to agriculturists and also to manufacturers. The extent to which flax might be cultivated in this country must, in a great measure, depend upon the facilities which the neighbourhoods afforded for getting the produce to the market. No doubt railways had greatly contributed to those facilities, and might make flax a profitable crop now where it was not so formerly. It was also necessary to be within reasonable distance of seed-crushing establishments; for though the seed might be used as food for cattle without crushing, by mixing it with chaff, still the most profitable use of it was when the oil was extracted by crushing, and the cake used as cattle food. With regard to the economy claimed by Mr. Young in the use of the machines he had described, it was stated that that which cost about 14d. per stone could be done for 5d. by this machine; if so, that was an enormous economy; and from what he had seen of the operation of the model the work appeared to be well done and the fibre uninjured. Certainly, if this machine were as successful as it appeared likely to be, it would sufficiently remunerate the inventor, irrespective of any patronage or aid from Government. His own opinion was that prizes offered by Government would never lead to important inventions. Any premium which the Government could give for a really valuable invention would be insignificant compared with that which would be derived from its commercial success. There had always been great difference of opinion on the subject of the Patent Laws, and he was not going to enter upon that this evening further than to say that in his judgment, if they could not be maintained on the ground that they were for the benefit of the country generally, and not merely of the inventor, he did not think they could be upheld. He was sure the meeting would agree with him that Mr. Young was entitled to their cordial thanks for his paper.

The vote of thanks having been passed,

Mr. YOUNG acknowledged the kind manner in which his communication had been received by the meeting. He thought it most important that local agricultural societies and landowners should stimulate the growth of flax in this country. The severe lesson which we were

taught by the late American war, in reference to cotton; was, he thought, sufficient to show the importance of our being as far as possible independent of foreign countries for raw materials of this character. He had been much gratified by the approval of this machine which had been expressed by so eminent a practical mechanician as Mr. Pothergill. The work done by the little model before them bore no comparison to what the machine itself effected. It merely served to illustrate the way in which the thing was done. With reference to Mr. Comabee's remarks he (Mr. Young) was happy to hear that Mr. Dickson, who had been trying his hand at this matter since 1851, had at length arrived at what he regarded as a successful result. He was informed that the weight of that machine was from six to eight tons, while that he had described weighed only about 5 cwt. The objection he had heard to Mr. Dickson's machine, so far as he understood it, was that it required that the flax should be passed through it twice to accomplish the complete breaking of the shive, only one side being broken at a time, whereas, in the machine he had described, the straw might be passed through very rapidly, and the process of breaking the shive was thoroughly effected by one operation. He agreed with the Chairman as to the great importance of growing flax where there was easy means of access to and from the mills. He might add that one great point in favour of the machine he had described, as regarded its application in agricultural districts, was the fact that it entirely dispensed with the necessity for skilled labour. With regard to what had fallen from Mr. Hancock, he did not think flax was a more uncertain crop than any other. The ground might be unsuitable, and an unfavourable season might retard the crop and lessen the yield, but it was no more uncertain in that respect than wheat, or any other crop. To return to the subject of the machine, the figures he had given were not the result of experiment only, but of actual work done by it. He had seen it in working for several months, and he was altogether so pleased with its operation, that, without having the slightest pecuniary interest in it, he was anxious that it should be brought before the public, and he had taken that task upon himself.

Proceedings of Institutions.

PENDLETON MECHANICS' INSTITUTION.—The sixteenth annual report states that considerable progress has been made. The finances of the Institution bear a more favourable aspect; the receipts have been £280 8s. 8d., and have exceeded the expenditure by £65 0s. 0½d., thus reducing the debt to £39 11s. 3d. During the year the directors have lost the services of some active members of the board by change of residence. The loss of the services of Mr. C. D. Cartwright and Mr. Allcock is especially regretted. The number of members of the Institution is 235, an increase of 62 on the former year. In the female class, which is taught gratuitously by the Misses Phillips, the pupils make rapid progress. The number on the books is 24; the average attendance 16. In the adult male class the attendance has been very satisfactory. The number on the books is 40; the average attendance 20. The juvenile male class has been well attended. Particular attention is given to imparting a fair handwriting, and the reading lessons are chiefly in English History. Elementary arithmetic is also taught. The number on the books is 29; the average attendance 18. In the drawing class the number on the books is 13; the average attendance 9. In the French class, the number on the books is 15; the average attendance 8. The chemistry class has been taught by Mr. Hartley, a Government science teacher. The number on the books is 11; the average attendance 7. In the short-hand class, which is of comparatively recent establishment,

the number on the books is 10; the average attendance for the first of April; no particulars are added, but it is understood that there will be no state ceremony. A large number of workmen are employed in getting the grand vestibule ready for the opening day; the wood work on the two sides, which form the boundaries of the French and English sections, is finished, with the exception of the last touches of the decorator; and the stained glass of the two countries begins to make a very handsome show, that which is already in place is fine in colour, harmonious in tone, and solid as regards method of treatment. These windows will bring French and English into direct competition, and, judging by what is visible, each has a formidable rival in the other. The clerestory windows of the vestibule are admirably adapted for the purpose in every respect, though of course the two sides are not equally advantageous in respects light.

PARIS UNIVERSAL EXHIBITION.

The opening of the Exhibition is officially announced for the first of April; no particulars are added, but it is understood that there will be no state ceremony. A large number of workmen are employed in getting the grand vestibule ready for the opening day; the wood work on the two sides, which form the boundaries of the French and English sections, is finished, with the exception of the last touches of the decorator; and the stained glass of the two countries begins to make a very handsome show, that which is already in place is fine in colour, harmonious in tone, and solid as regards method of treatment. These windows will bring French and English into direct competition, and, judging by what is visible, each has a formidable rival in the other. The clerestory windows of the vestibule are admirably adapted for the purpose in every respect, though of course the two sides are not equally advantageous in respects light.

The two commissions are naturally intent on showing some of their choicest specimens at this spot, and the sides of the grand vestibule will be occupied, to use the old exhibition term, by series of trophies. The most conspicuous for the moment is a collection of casts of decorative sculpture, from South Kensington; the reconstruction of the celebrated pulpit by Nicolas Ponce; younger; portions of the famous *Gloria* of St. Louis, Spain; and a Venetian tomb.

The machinery in the British department is not getting into something like order, but there still remains a great deal to be done before many of the machines are ready for work. The boiler house is now practically finished, and the steam piping, shafting, &c., nearly completed.

The American coal-burning locomotive, with its boiler and chimney covered with German silver, is now completed. The driving and trailing wheels are 5 ft. 6 in. in diameter, and are coupled together. The front part, with its cow-catcher, is mounted on a four-wheeled truck. The tender is also on two four-wheeled trucks. The cylinders are outside, 16 in. in diameter, with 22 in. stroke. The "cab," or housing for the engine driver, is in polished wood, in true American fashion, and is well finished. The rails upon which the engine stands are laid with Dering's patent rail-fastenings.

The Chemin de Fer de l'Est send one of their two-storey carriages, to accommodate eight passengers, first, second, and third class.

The English barrack hut is now being fitted up. It contains compartments for the exhibition of various articles of barrack and hospital furniture and fittings, and contains specimens of a soldier's barrack room, lavatory, sergeant's or married soldier's quarters, a troop stable, recreation room, hospital ward, and offices attached to the hospital.

In the Swiss annexe, Messrs. Escher, Wyss, and Co., of Zurich, have completed a pair of 120-horse power engines, for lake or shallow river navigation. Here also is exhibited a good deal of agricultural machinery.

The Dutch are exhibiting a great deal of railway plant in a building for that purpose in the park.

In the French marine engine building are the three cylinder 960-horse power engines for the *Friedland*, made at Indret. Four of the boilers are being fixed. The cylinders are 82½ in. in diameter, with 5 ft. stroke. The propeller is four-bladed, 19 ft. 6 in. in diameter. These engines will be employed during the Exhibition for the purpose of pumping water from the Seine to supply the fountains, &c., in the park.

The English marine engines are not so forward. Messrs. Penn's screw trunk-engines, of 360-horse power, are at last being erected. The Société John Cockerell, of Sarnia, are putting up a large vertical blowing engine with 9ft. cylinder.

In the way of decoration the iron work of the British section is being relieved with gold lines, which will harmonize well with the olive-green colour of the iron, the rich dark crimson draperies, and the black and gold of the majority of the cases. But the most novel and characteristic piece of decoration is that adopted by the British commission for the eighty great windows of the machinery gallery; these are being rapidly filled with transparent blinds, stretched on frames, each recording the fame of a British inventor or improver. A picture of the machine itself occupies the centre of the blind, and above and below is the description of the invention and the name of the inventor, with dates and other particulars. A better method of staining this immense range of windows could hardly have been adopted, and the list will supply a remarkable chapter in the catalogue of the English section of the exhibition.

The collection of books, periodicals, and newspapers published in the United Kingdom and its dependencies in the course of the year 1866 begins to attract attention; it is one of the noblest exhibitions that Great Britain can make, the only drawback being that in this case it is impossible to show much more than names and titles. But Dr. Johnson said that the next thing to having read a book was to know where to find it, so that those who are not yet acquainted with our literature will at any rate have an opportunity of learning something about it this year. One branch of the subject, that of illustration, is well exhibited by specimens under glass. The books amount to about \$000, and the newspapers to nearly 1200; the number of the periodicals and serial works is also large.

Workmen are now occupied in fitting iron doors to the English picture and retrospective galleries; when this is done, which will be in a day or two, the works of art may be at once arranged, and the chance of accident will be reduced to a minimum.

The English carriages make a good show, though unfortunately placed in the machinery gallery, while those of France have a separate department. There are 24 exhibitors, who show nearly 40 carriages of various kinds, from a dog-cart to a dress landau.

The Trinity Board has a fine exhibition. Besides the magneto-electric lighthouse, and two steam fog-horns, which will be found in the garden, there are, in the machinery department, a first-class fixed catadioptric Fresnel lens, with shadowless lantern; a first-class revolving lens, with improved clock-work, the glass work by Chance, of Birmingham; one fixed, and one revolving floating light; a large number of models, including Stevenson's holophotal reflector, composed entirely of glass arranged at the angles of total reflection, and a complete system of lenses, lanterns, buoys, beacons, and accessory apparatus and fittings, the whole making a most interesting exhibition.

India and the colonies promise well; the show of the former is only limited by the area allotted to it, as the objects at the disposal of Dr. Forbes Watson may be said to be unlimited in number, and unrivalled by anything in the Exhibition for beauty of colour and workmanship.

The Canadian court will present a peculiar appearance; the columns of the building have been encased in woodwork, which will be made to represent trunks of trees; a transparent false ceiling will embrace the upper part of these trees, the whole being arranged, with the aid of the decorator, to represent a tent or pavilion in the forest. Within this enclosure will be a fine collection of the timber, ores, and other products of the country, including a gigantic squared yellow pine, 60 feet long, and containing 200 cubic feet of timber. Canada is one of the few colonies that will show machinery, several printing presses and other examples

having been sent over. There will also be several specimens of carriage-building, including a trotting carriage of excessive lightness, called *la planche* by the French, and the "spring-board" by English Canadians; two sledges, and a railway sleeping-carriage, on the American system.

The fittings and decorations of all the foreign courts are nearly completed, and, in many cases, important contributions are brought to light. One of the most conspicuous and most beautiful is a mosaic picture, of large size, in the Russian court, the design, a group of the saints of the Russian calendar, is by Professor Neff, of the Academy of the Beaux Arts of St. Petersburg; the mosaics are in enamel, and the effect of the work is extremely fine.

The Italian courts are being rapidly completed, and in that of the Papal States a magnetic meteorograph occupies a central position; this is the invention of the Reverend Father Secchi, Director of the Roman Astronomical Department.

The States of Northern, Central, and Southern America are setting out their goods; and the decorators are now finishing off the Chinese and Japanese courts in gold and vermillion, and all the brightest possible hues, the whole being in the style of the countries whose productions are to be exhibited there.

Amongst the new buildings in the Park, the Chinese has become conspicuous by its high square roof, with up-turned corners; the Pavilion of Marengo approaches completion, and has a very marked and peculiar character; while near it rises a large pyramidal building in two stages, which will contain a collection of the antiquities and products of Central America; the fine group of Egyptian buildings is now finished externally, and nearly so inside also, and they are not only striking but remarkable for their solidity and elegance; at another corner of the park a collection of Austrian buildings has sprung up with wonderful celerity. All the out-of-doors work is, in fact, as forward as the weather would permit, and the few days which intervene between this and the opening of the exhibition will doubtless produce immense changes.

The arrangements of the gallery to receive the illustrations of the History of Labour, are nearly all completed, and the contributions are arriving. The Bishop of Saint Brienc has collected a number of the most precious objects belonging to the churches of his diocese. The authorities and amateurs of Toulouse send a large and rich collection of antiquities, of the Gallo-Roman period. Rheims sends the precious relics belonging to her cathedral; and there are many fine specimens of ancient tapestry and objects of art contributed by the museum and public library of the old city, and by private persons. The Bishop of Clermont has collected the most beautiful specimens of ecclesiastical plate and ornaments in the Puy de Dôme; and the Bishop of Limoges, the Archbishops of Sens, Arras, and Bourges, have collected similar specimens of art manufacture in their several dioceses. The local committees of the departments of the Rhône, the Nord, and the Seine Inférieure have made magnificent collections from the treasures of the churches, museums, and private collections of their districts. Amongst the most remarkable objects in the French section of this department of the exhibition will be the shrine of Saint Chaubin, considered to be the most important specimen of French goldsmith work of the latter part of the thirteenth century. The representatives of the commission at Nîmes and Poitiers are said to have made a rich and rare collection. Large contributions are arriving from abroad, but it is much to be regretted, if the report be true, that Belgium and Prussia will not send anything to this section of the exhibition.

The Salle de Conférences, or lecture room, spoken of long since, is now in hand and will soon be finished.

Ten thousand French workmen and workwomen have met and elected the delegates to represent them at the exhibition; the number of representatives thus appointed

is 305 men and 10 women. Each trade or batch of trades had to elect a number of delegates in proportion to its numerical strength, thus the *ouvriers* of the coach, wheelwright, harness-making, and other allied trades named twelve representatives; the bronze founders and workers, and the cabinet makers and other workers in wood, each eight; the letter-press printers, typefounders, and stereotypers, six; the jewellers and goldsmiths, the engineers and mechanicians, the founders, turners and metal workers, the tool and nail makers, and the tanners and leather dressers, each five delegates, and the other groups numbers diminishing down to one. The ten female delegates represent the seamstresses, the stay-makers, artificial florists, the workpeople of the linen warehouses, and the dressmakers, each electing two delegates.

The Exhibition will, like its predecessors, give rise to a considerable number of publications, besides the official catalogues and handbooks. The most important yet announced is entitled "Études sur l'Exposition de 1867," by M. E. Lacroix, editor of the *Annales du Génie Civil*. The plan of this work is very elaborate, embracing all the subjects connected with civil engineering, construction, and scientific manufactures, and the list of contributors includes a large number of scientific writers of high standing.

M. Ch. Kerdôl, editor of the *Moniteur Vinicole*, and a practical farmer, announces a special publication on the agriculture of the Exhibition. Both these works are to be published in parts, and are announced to appear in the month of April.

The post office, telegraph office, and a number of restaurants, cafés, and other establishments for the accommodation of the public are now open, and many more will be so in a day or two. The weather is improving, and the prospects of the Exhibition improving with it.

Fine Arts.

RAPHAEL DRAWINGS, &c.—A series of photographs, perhaps unexampled for completeness, from the most celebrated collections, public and private, may now be consulted by students in the National Art Library, Kensington. The series comprises photographs from 90 drawings in Venice, 80 in Vienna, 54 in Windsor, 188 in Oxford, &c., &c. In fact, authentic copies of at least 600 examples of Raphael's scattered studies in ink, chalk, silver-point, and sepia, are now for the first time brought together for examination and collation. The Department of Science and Art, it is known, have for a considerable period entertained the idea of making a grand exhibition of the works of Raphael. This assemblage of photographs may do something to advance the project. The cartoons are already on the spot. "The Raphael Room" which has for some months been open, though as yet more tentative than complete, serves to indicate the mode in which the works and genius of Raphael will admit of illustration. It was a favourite idea of the late Prince Consort, that the three great Italian masters, Leonardo da Vinci, Michael Angelo, and Raphael, should receive systematic and adequate exposition. What progress had been made towards the realization of this intention at the time of Prince Albert's death, may be judged from the photographs, engravings, &c., after Raphael, which fill nearly fifty volumes now in the Queen's library, Windsor Castle; and it was by the authority and under the influence of the Prince Consort, that a large number of the photographs now seen in duplicate at Kensington, were originally executed. There was scarcely a collection, save that in the Biblioteca, Milan, not included in the series. This important collection is still unrepresented at Kensington. A trustworthy photograph from Raphael's cartoon of the "School of Athens" in Milan, would indeed be of great value.

COLLECTION OF ART FAC-SIMILES.—The Belgian Government has decided on adding to its Museum of Antiquities a collection of fac-similes and tracings of ancient mural painting and the most interesting stained glass in the country. As a nucleus for this new museum of art, the authorities have purchased of M. Capronnier, of Brussels, a series of 87 cartoons of the most celebrated painted windows of the churches of St. Gudule, at Brussels; St. Jacques, St. Martin, and St. Scroais, at Liège; St. Wandra, at Mons; St. Pierre, at Louvain; and of the cathedrals of Tournay and Antwerp.

ARCHITECTURAL CONFERENCE.—The Society of the Architects of France invite their *confrères* of all the world to an international conference, to be held in the month of July next, with the object of taking into consideration the methods in use in architectural education, and all questions connected with the subject, and especially to inquire into the tendency of the modern architecture of all nations.

DISCOVERY OF A PICTURE BY VANDYCK.—A St. Cecilia, by Vandyck, said to be one of the finest productions of the artist, and in admirable condition, has been discovered in an extraordinary manner at the village church of Caelevoet, between Uccle and Beersel, in Belgium. Repairs having been necessary, the walls of the little church were stripped, when the picture was found between two boardings.

Manufactures.

TUSCAN COTTON MANUFACTURES.—The manufacture of woven cottons for the dress of the lower classes in Tuscany causes a considerable importation of cotton thread, of which the English manufacturers have the exclusive monopoly. These fabrics, which bear in the country the name of *bordato* and *fustagno*, are made up in nearly all parts of Tuscany, but more especially in the lower valley of the Arno, at Pisa, Pondera, Navacchio, Empoli, &c. At these towns there are more than 100 hand-looms; at present none are driven by steam power. A great number besides are scattered through the country, especially where the straw hat industry fails. Women find in this employment, which allows them to attend to the cares of their household, a useful resource for their families. According to the last statistics published by the grand ducal government, the only one which makes mention of this industry, the number of existing looms in 1856 is estimated at 150,000. Since then they have increased to a considerable degree; their number may now be computed at from 175 to 180,000. The cotton employed in this industry comes, as cotton thread, direct from Manchester and Liverpool to Leghorn, where it is bought by the principal manufacturers, who have it dyed, and distribute it to the weavers, who again distribute it to those who, having no loom, are employed in winding the thread and preparing it for weaving. The work is paid by the piece, at from 7 to 9 centimes the Tuscan ell ($\frac{1}{2}$ of this measure, is equal to a metre). The weaver can earn from 42 to 56 centimes per day. The winders are also paid by the piece, and cannot earn, working from morning to night, more than 35 to 42 centimes per day. Fabrics of this kind are sold in all the markets and fairs of Tuscany, and the price varies, according to quality, from 84 centimes the Tuscan ell to 1 franc 20 cent. All colours are employed for the fabrics intended for women's dress, deeper colours being used for men's wear—grey, deep blue, or the natural colour of the cotton. The annual manufacture is valued at more than twenty million francs, and the importation of cotton at more than eight million francs. There are at this present time, in the warehouses of Leghorn, nearly four million francs' worth of cotton thread intended for this industry, imported entirely from England. Since the slight rise in cottons, which took place recently, the weavers have abstained from making pur-

chases, in the hope of a speedy fall in price. Nevertheless, the looms are not idle at the present time, owing to the foresight of manufacturers, who, fearing competition with the factories of Northern Italy, and particularly with those mills which have just been erected in Bologna, have kept a great quantity of cotton thread in reserve. One manufacturer, M. Manetti, a very rich proprietor in the province of Pisa, employs at his factory more than 6,000 persons of both sexes—dyers, winders, and weavers.

Commerce.

ARTIFICIALLY COLOURED TEA.—It appears, by the *Produce Markets Review*, that a complete revolution has taken place in the distribution of the Japanese crop, for whereas a few years ago the greater part went to England and China, and little more than one-fifth to the United States, the latter now monopolize nearly the whole supply. The explanation of the diminution of shipments to England is probably that the public here will not buy natural green teas, but prefer them artificially coloured with Prussian blue and gypsum. During the American war, the taste of the English public was met by sending the pure Japanese tea to China to be dyed green; but the Americans, who drink a great deal of Oolong, show great partiality for the fine-flavoured Japan teas. That Japan tea was ever sent in any considerable quantity to China, suggests the old proverb about sending coals to Newcastle. It may, as we have said, have been sent there to be coloured, but we should have thought that the Japanese, who at least equal if they do not excel the Chinese in manual dexterity, could have performed this process at home. They may do so now, for all we know: but it would be more pleasant to suppose that the Americans drink the tea in its uncoloured state.

Colonies.

BANKING IN MELBOURNE.—In the year 1856 the eight banks then existing held, on an average, coin to the amount of £2,798,257, and had notes in circulation to the extent of £2,328,226; but, notwithstanding the increase of trade, and the development of resources then unknown, the note circulation and the stock of coin has gradually declined. The value of coin held on the 30th June, 1866, was £1,259,767, and their notes in circulation but £1,278,030, showing a decrease in the last ten years of £1,538,490 in the bank stock of coin, and of notes in circulation £1,050,236; but during this period the deposits have continued to increase. In 1856 the average amount of deposits held was £5,967,330, and in the quarter ending June, 1866, they were £8,799,982. This reduction has been going on with increased profits and capital, showing that there is no insolvency in the matter. The long drought has, doubtless, contributed to the present scarcity of money. The precise amount of loss caused by the drought is unknown, but it is estimated at about £700,000.

Notes.

EDUCATION AND CRIME.—Lord Chief Justice Bovill, in his charge to the grand jury at the assizes at Lewes—alluding to the remarkable distinction between the calendar for the eastern and western divisions of the county, in this respect, that few of the prisoners in the former could read and write, whereas most of those in the latter could, and that there was much less crime in the latter than the former—observed upon the great importance of education as a means of preventing crime. He remarked upon the terrible temptations to crime

which were presented by idleness to ignorance. Persons unable to read, and thus shut out from a whole world of innocent entertainment, when they found themselves idle and unemployed, what were they to do? It was obvious that such persons were exposed to peculiar temptations to crime, simply for the reason that they did not know what to do with themselves when unemployed. This was peculiarly the case in agricultural districts, and it strongly showed the extreme importance of educating the children of the poor, especially of the agricultural population. He was aware of the temptation which there was to keep children from school when they were able to earn money, but this only showed the importance on the one hand of getting them to school as early as possible, and, on the other hand, of persuading them to attend evening schools, at all events on some days in the week.

Correspondence.

THE FOOD COMMITTEE.—SIR,—I have read with great interest the papers on Food published in your journal on the 8th and 15th of March; but with reference to the extract of meat, I cannot understand how Dr. Thudichum arrives at his conclusions marked *a, b, c*. These conclusions seem to me singularly at variance with the facts of the case. 1st. As to "convenience" of use. The "extract of meat" is sold in 2 oz. pots, which may remain open, without the slightest protection, for days, and yet no change or decomposition takes place. As to loss by "sub-division," there is none whatever; the extract certainly sticks to the spoon, like treacle, but of course is all dissolved and taken up by the water used. 2nd. As to the supposed "necessity of storing in a cool larder." The sample of extract sent by me to the Committee on Food was made in New South Wales, in Nov., 1866, when the thermometer averaged 85° in the shade. It came home in the hold of a P. and O. steamer, through the Red Sea, the heat in the hold averaging over 90°.—Liebig states (*Annals of Chemistry*, vol. 133, p. 125, year 1866): "I have now before me samples which have been preserved 15 years in vessels stopped with a simple cork or paper, and which exhibit no sign of deterioration." So much for the necessity of a cool larder. 3rd. As to the "intelligence" required in using the extract of meat. About the same degree of intelligence is required as in making tea, perhaps hardly so much, as it is not absolutely essential that the water used should be actually boiling. The following is from a Report by Dr. Parkes, Professor of Hygiene, Army Medical School, and published by the authority of Government:—"In all our trials even small quantities produced a feeling of support and vigour which ensued very soon after it was taken. For the military surgeon it is likely to be very useful in active service, not only for the sick and wounded, but for healthy men. Its small bulk, *ease of cooking*, savoury taste, and great restorative action, would make it most useful in rapid expeditions." I may add that in Mr. Chester's remarks, published in last week's *Journal* (p. 274), he speaks of the preserved boiled beef as "Tindal's"; it should be described as produced by the "Australian Meat Company (Limited)."—I am, &c., C. G. TINDAL.

MEETINGS FOR THE ENSUING WEEK.

- MON.—R. United Service Inst., 54. Prof. W. J. Macquorn Rankine, "The Economy of Fuel, comprising Mineral Oils." Society of Arts, 8. Cantor Lecture. Mr. John Hullah, "On Music and Musical Instruments." Farmers' Club, 54. Discussion on "The Desirability of a Board of Agriculture as a Government Department." Introduced by Mr. Nockolds. GRANTS OF PROVISIONAL PROTECTION.

- Animal size, packing, &c.—697—J. C. Martin.
 Baling bands, couplings for—630—A. V. Newton.
 Belts, fastenings for—630—A. V. Newton.
 Bituminous substances, distilling—650—W. Young and P. Brash.
 Boilers—609—T. Beeley.
 Bottles, &c., cases for—615—G. Withy and J. F. Cotterell.
 Brackets, adjustable—618—E. Wells and W. Pryor.
 Breech-loading fire-arms and cartridges—647—H. Haaschke.
 Breech-loading fire-arms, cartridges for—660—G. H. Daw.
 Bridle bits—638—H. W. Achgels.
 Burners, regulating the supply of gas to—577—W. C. Thurgar.
 Calico printing machines—628—W. Tomlinson.
 Carriages—622—G. H. Morgan.
 Casks, bushings for bung holes of—648—W. Hurrell.
 Chains, &c.—625—J. G. Taylor.
 Clockwork, winding up—632—C. E. Brooman.
 Compasses, protecting the needles of—676—J. S. Gisborne.
 Drying cylinders, regulating the speed of—614—A. Rupp.
 Eggs, hatching—640—S. Wortley.
 Fabrics, producing borders on—585—S. Frank and B. Gooddy.
 Fagots—640—T. Humphreys.
 Fan blowers, actuating—646—W. Clark.
 Fibrous substances, preparing—668—J. Horton, jun.
 Fibrous substances, preparing, &c.—599—A. and H. Illingworth.
 Fire-arms, breech-loading—694—W. R. Pape.
 Fire-arms, breech-loading—599—M. A. F. Mennons.
 Fire-arms, repeating breech-loading—619—G. Haselstine.
 Flax stripping machines—596—W. E. Gedge.
 Fluids, &c., raising, &c.—686—W. B. Nation.
 Gas—624—J. Thompson.
 Glove fastenings—656—J. H. Johnson.
 Hook, a compound safety disengaging—673—J. C. Broadbent.
 Hydro-carbon oils—611—A. S. Moore.
 Hydro-carbons, treating—563—A. A. Croil.
 Inkstands—657—J. Piddington.

- Inserts, destroying—666—E. Newington.
 Iron bands, fastening—564—T. J. Binfield.
 Knobs, securing—583—T. Hyatt.
 Lace—644—S. Butler.
 Lamps—679—G. Glover.
 Lamps, miners' safety—617—G. Bowley.
 Light, artificial—566—A. G. Chalus.
 Liquids, cooling and freezing—625—H. C. Ash.
 Liquids, transporting, &c.—582—M. Goss.
 Locomotives, &c., indicating the speed of—681—F. W. Jen.
 Locks—654—F. Pope.
 Locks, &c., knobs for—664—S. Hawthorn.
 Materials, conveying, &c.—620—J. R. Breckon and E. Dm.
 Metallic ores, reducing, &c.—653—S. C. Salsbery.
 Mines, destroying explosive gases in—645—J. Harbert & T. Goss.
 Motive power—278—1. Bagg.
 Motive-power engines—652—A. McCallum.
 Mouldings, cutting, &c.—604—B. Thompson.
 Needle cases—603—J. W. Lewis and G. Archbold.
 Oils, utilising—616—J. E. Duyck.
 Optical illusions, producing—629—H. W. Hallatt.
 Ovens—662—J. Buhrer.
 Porcelain—642—W. E. Newton.
 Railroad carriages, starting—630—W. Clark.
 Railway axles, bearings for—673—L. Thöde.
 Railway signals, &c.—538—J. Saxby and J. S. Fanner.
 Reel frame and thread cutters, combined—598—R. E. Ka.
 Safety gauges, self-acting—691—J. A. Coffey.
 Screws and bolts—650—A. V. Newton.
 Sewage, treating—679—W. Parry and J. Freeman.
 Sewing machines—661—E. T. Hughes.
 Sewing machines—636—I. Dimock and J. Gresham.
 Shirts, &c., metallic fronts for—603—J. M. Stanley.
 Steam and gas engines—671—A. V. Newton.
 Steam boiler furnaces—634—W. Heginbottom.
 Steam boilers—626—E. Storey.
 Steam boilers—663—J. Whitaker.

Journal of the Society of Arts.

FRIDAY, APRIL 5, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

APRIL 10.—"On the Operation of the Chain Cables and Anchors Act, 1864." By ROBERT GALLOWAY, Esq., C.E., Chief Surveyor of Steam Ships and Examiner of Engineers, and Inspector of Proving Establishments, Apparatus, and Machinery.

APRIL 17.—*Passion Week.* No MEETING.

CANTOR LECTURES.

The next Lecture of the Course, "On Music and Musical Instruments," by JOHN HULLAH, Esq., will be delivered as follows:—

LECTURE VI.—MONDAY, APRIL 8.

MUSICAL INSTRUMENTS (*continued*).—Medieval Instruments, &c.

Mr. Hullah having found it impossible to deal with so extensive a subject as musical instruments in the two lectures originally assigned to it, it is proposed to extend the course by one or possibly two lectures. Particulars will be duly announced.

The lectures commence at eight o'clock, and are open to members, each of whom has the privilege of introducing one friend.

FINAL EXAMINATIONS.

Owing to the death of the Dean of Hereford, Examiner in Domestic Economy, and to the resignation of Mr. John Marshall, F.R.S., Examiner in Animal Physiology, the Council have appointed Examiners as follows:—

Domestic Economy ..	{ E. Carleton Tufnell, Esq., one of Her Majesty's Inspectors of Schools.
Animal Physiology ..	{ Michael Foster, Esq., M.D., Teacher of Practical Physiology in University College, London.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Countts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

The following letter was addressed, by desire of the Committee, to the Secretary of State for the Home Department:—

18th January, 1867.

SIR,—The Society for the Encouragement of Arts, Manufactures, and Commerce, having had its attention directed to statements put forth under the authority of the Privy Council and the Poor Law Board, to the effect that the working classes of this country are insufficiently fed, has appointed a committee to inquire and report on this subject with a view to ascertain how far the existing supplies may be better utilised, and how far they may be supplemented from new sources; and from such an enquiry it seems impossible to exclude the question, how far the law is effectual to prevent or to punish the fraudulent adulteration of food and the use of false measures and weights in the sale of food.

The newspapers have lately been drawing attention to numerous convictions which are stated to have been obtained in the metropolitan parishes against publicans, butchers, bakers, grocers, and other vendors of food, for having used false weights and measures; and the Society of Arts' Committee on the Food of the People would esteem it a great favour and an important assistance in their difficult work if you would have the kindness to give directions that they may be furnished with returns showing the number of convictions that have been obtained in respect of such offences in the several parishes of the metropolis within a certain definite period (say) the year 1866. The names of the offenders are not asked for, but merely a return showing the number of the convictions, the nature of the offences, and the punishment awarded, in the several parishes of the metropolis.

I have the honour to be, sir,
Your obedient servant,
P. LE NEVE FOSTER,
Secretary.

The Right Hon. Spencer H. Walpole, M.P., one of Her Majesty's Principal Secretaries of State.

To this the following reply has been received:—

Whitehall, March 29th, 1867.

SIR,—I am directed by Mr. Secretary Walpole to inform you, with reference to your letter of the 18th January last, that application has been made to the vestry clerks of the several parishes in the metropolis for returns of convictions in their respective parishes for using false weights and measures; and I am to transmit to you, herewith, for the information of the committee of the Society of Arts on the Food of the People, the returns which have been received from such of the vestry clerks as have not objected to furnish the information desired by the Society of Arts.

I am, Sir,
Your obedient servant,
BELMORE.

The Secretary to the Society of Arts.

The returns referred to will be laid before the Committee, and the substance of them will appear in a future number of the *Journal*.

The following letter has been addressed to the Secretary of State for Foreign Affairs:—

30th March, 1867.

MY LORD,—The Society of Arts has appointed a Committee on the food of the people, the particulars of which are explained by the enclosed printed paper.

The Committee are about to take up that part of their investigation which relates to the adulteration of food,

and they are anxious to learn what regulations or laws are in force under this head in other countries, and how far they are found effective; and I am directed to ask if your Lordship would, through Her Majesty's representatives abroad, procure for the use of this Committee information in illustration of the provisions, action, and effect of the laws against frauds, by adulteration, or by the use of false weights and measures in the sale of food, in France, Belgium, Holland, Switzerland, Denmark, Norway, and Sweden, Prussia, and the United States.

I have the honour to be, my Lord,

Your Lordship's most obedient servant,

P. LE NEVE FOSTER.

Secretary.

To the Right Hon. The Lord Stanley, M.P.,
Her Majesty's Principal Secretary of
State for Foreign Affairs.

The following reply has been received :—

Foreign Office, April 2, 1867.

SIR,—I am directed by Lord Stanley to acknowledge the receipt of your letter of the 30th ultimo, and to state to you that his Lordship will be happy to instruct Her Majesty's Representatives in the countries therein designated to endeavour to procure for the use of the Society of Arts the desired information in regard to existing laws on the subject of frauds and adulteration in articles of food. I am, Sir,

Your most obedient humble servant,

G. HAMMOND.

P. Le Neve Foster, Esq.

CANTOR LECTURES.

"ON MUSIC AND MUSICAL INSTRUMENTS." By JOHN HULLAH, Esq.

LECTURE V.—MONDAY, APRIL 1.

MUSICAL INSTRUMENTS.

In his fifth lecture Mr. Hullah entered on the consideration of musical instruments. He said that were he to ask any musically-cultivated member of his audience how many instruments, differing so much from one another as to have been thought worthy of different names, there was any authentic account of, he would probably answer—perhaps as many as fifty. In a list which had recently come under his eye, he (Mr. Hullah) had found that, inclusive of acoustical apparatus, the number amounted to about 400; and this list was probably not complete. This statement would hardly be so surprising as another—that all these instruments, of whatever nation, age, or material, were reducible to two—the wind instrument, and the instrument of percussion—the pipe and the string. The motion which results in what is called sound, must be communicated to the air in one of two ways—by setting in vibration either a column of enclosed air, or some other more palpable, yet still elastic body. Indeed, perhaps, in strictness of of speech, there is but one instrument; for the column of air in a pipe is just as much set in vibration by percussion as is a string, a sheet of parchment, or a metal plate; but the modes of percussing a column of air, and any other elastic body, are so different as to render the common division of musical instruments indispensable. Of both divisions there are two distinct families; those in which varieties of pitch are produced by multiplication of pipes, strings, or other vibrating portions, and those in which varieties of pitch are produced from some one or more pipes (generally only one) or strings (generally more than one). Of the first family, the type among wind instruments is the mouth-organ, or pipe of Pan; and among stringed instruments, the harp. Of the second family, the type, among wind instruments, is the flute-à- bec; and amongst stringed instruments, the guitar. Pipes, as well as strings, have been made of various materials, vegetable, mineral, and even animal.

Thus, pipes are made of wood, metal, crystal, and bone; and strings of flax, metal, silk, and catgut. Other instruments of percussion, of a lower type, are made of wood, dried vegetables, and skins. Before describing the modes, which were very few, of setting these instruments in vibration, Mr. Hullah would be glad to remove a very common misconception as to the causes of sound in them. The *voice* of an instrument is the air vibrating inside it, not the instrument itself, which latter simply contains and shapes the air, thereby enabling it to vibrate. The vibration causes the sound, which the instrument augments, and enables us to govern. This fact enables us to distinguish the two classes of instrument very decidedly. In many wind instruments the principal vibrating body is the air inside them, which is acted upon directly by the human breath; while, in an instrument of percussion, we have the string to set in vibration before we can move the air contained in the body of the instrument. A wind instrument has generally two constituent parts—a pipe, or sounding-board, and the air in it. A stringed instrument has three—a sounding-board, the air in it, and strings. In producing sound from a stringed instrument, therefore, we have one more step to make than in producing sound from a wind instrument; and this is one of many reasons for thinking wind instruments the more ancient of the two. But, whichever be the more ancient, both are of immense antiquity; as, indeed, are all essentially different modes of producing musical sound. A really new quality of sound has not been invented for ages. Improvements in the strength or sweetness of these qualities have been and still may be made; but, whether the oboe reed be an inch or an eighth of an inch wide, whether the flute have two holes or ten keys, the instruments are essentially the same now as they were three thousand years ago. Though no record of the order in which the primeval instruments came into being has reached us, it is not difficult to indicate what this order is likely to have been. The craving for rhythm is stronger in all of us than that for time. Monotonous sounds, iterated in an orderly manner, are more easily appreciated and remembered than sounds, in themselves more musical, whose lengths bear no proportion to one another. If this be so, monotonous or pulsatile instruments must be prior to, and therefore more numerous than, all others. The number and variety of these instruments in the world is incalculable. Pipes probably followed these varieties of the drum, and pipes hardly more worthy than the drum to be called instruments. For, in its primitive state, every pipe has but one note. The production of several notes from the same pipe, like the production of several notes from the same string, was obviously posterior to the obtaining the same effect by the collocation of several pipes or strings of different dimensions. The mouth organ therefore is likely to be anterior to the typical flute, or oboe, whatever their forms may have been. The earliest stringed instrument is probably the bow; not the bow of the modern violinist, which is but a part of an instrument, but the bow of the ancient hunter and warrior. The bow-string, under favourable circumstances, gives an audible sound. The resemblance between the bow and the earliest harps certainly tends to verify the origin, not in itself improbable, thus assigned to stringed instruments. A slight thickening of the outline at one part is all that distinguishes the latter from the bow. This thickening marks the place of the sounding-board, the invention of which, like that of the line in musical notation, constitutes the first step in a long and most profitable journey. Most nations seem to have long had some instrument of the dulcimer kind formed of strings of different length and thickness stretched over a sounding-board. These strings were sometimes plucked by the finger-nail, a quill, or a piece of ivory, sometimes they were struck by hammers held in each hand. In the former case we have the type of the harpsichord, in the latter that of its successor, the

ianoforte. Next to the sounding-board the most important invention ever applied to musical instruments was the finger-board, without which we should, to this day, have wanted the whole family of bowed-stringed instruments. The knowledge of the division into aliquot parts of a musical string, implied in the application of the finger-board, argues a very high civilization. Such is what might seem to have been the natural order or course of discovery and improvement in musical instruments. Its probability is confirmed by history and historical monuments. Assyrian and even Greek instruments are chiefly known to us from pictorial or plastic representation; but we have not only representations of ancient Egyptian instruments, but some specimens of the instruments themselves. The Egyptian flutes which have been found are of wood; probably the earliest were made of bone. The Latin word *tibia* was applied generally to pipes not commonly made of metal. The Egyptian lutes were generally very long, and sometimes double. In Greek and Roman music, flutes played a most prominent part. They were made of box, of laurel wood, and even of brass, silver, and gold. Flutes were employed by the Greeks and Romans, not only as concert instruments, but to maintain the pitch of the voice in public oratory and theatrical representation. All recitation among the cultivated ancients would seem to have been musical. The enormous theatres, the vast public places of Greece and Rome, like the churches of the middle ages, were of dimensions altogether beyond the powers of the speaking, or so-called natural voice. Whatever associations there may now be with the monotone (the basis of musical oratory), its adoption originated in considerations thoroughly practical. All but the most practised orators, musical or unmusical, occasionally depress or elevate their voices too much; the ancients met this propensity by stationing near the orator a *tibicen*, or flute-player, who from time to time reminded him of the true oratorical pitch. In all Greek and Roman representations the *tibicen* plays on a double flute. It has been supposed that these instruments were often in octaves one with another; and the words *paræ* and *imparæ*, applied by Terrence to flutes, have been thought to justify this supposition. The words *dextra* and *sinistra*, used by the same author, would seem to refer to the hands by which each flute was sometimes held. It is not improbable that the larger flute was one-noted (a drone), while the smaller was pierced, and capable of something like execution. The Egyptian boatmen still use a double flute; and in India there is an instrument of this class blown, not by the mouth, but by the nose. But there is another class of instrument, the pipes of which are generally of wood, like those of the flute, but the sound of which is produced in a very different way. In both the cause of sound is the vibration of the column of air contained in the pipe, but whereas the tone of flute pipes is produced by a comparatively direct action of the breath on this column of air, that of reed-pipes, as they are called, demands the intermediate agency of a tongue, or a pair of tongues, of some elastic material, the vibration and beating together of which afterwards sets the column of air in the pipe in vibration. That which a string is to a sounding-board a reed is to a pipe. Dr. Burney, writing in the last century, thought that the ancients were unacquainted with the reed; but in some pipes from Egypt, in the British Museum, there are pieces of thick straw, or similar material, which a recent writer, Mr. Engel, thinks served for a similar purpose as the so-called reed in our oboe or clarinet. Indeed it is difficult to understand how, without a reed, a tube blown from the end, in the manner depicted on ancient monuments, could be made to sound. Of brass instruments, the type, the trumpet, is very ancient. As flutes, generally of wood, were sometimes made of metal, so trumpets, generally of brass, were sometimes made of other material. Hebrew trumpets, for instance, were rams' horns. The oldest representations give the trumpet, not as with us, doubly reversed, but straight, or very slightly curved. In pro-

cessions trumpets thus made, being too heavy for the performer to support, were rested on the shoulders of other persons, and in stationary performances on a frame. There are three modes of setting in vibration a musical string, and the result of each is the production, even from the same string, of very different qualities of sound. These modes are plucking or pulling it with the finger, the fingernail, a quill or a piece of bone; striking it with some kind of hammer; and abrading or rubbing it with a bow. With the first two of these modes the ancients were acquainted; of the bow it is probable that they had no knowledge; it is certain that they did not turn it to account. Of the plucked instruments the types are the harp, and the cithara or guitar. The lyre, through different in form from the harp, is but a variety of it. The cithara, identical in principle, and even name, with the guitar, is a very different instrument from the harp or lyre; and though, in the hands of the ancients who did not use the bow, it remained very inferior to the harp, yet its construction indicates greater mathematical science if not greater mechanical skill, and an admirable economy of means and appliances. Moreover its finger board was in very early times, it is believed, fretted; showing that the harmonic division of a string was understood. But it is as the founder of the violin-family that the cithara is most interesting to us. Many were the modifications needed to develop the cithara into the violin, yet no one would for a moment question their relationship. The harp, however, as it was the most perfect, was the most honoured of very ancient instruments. Numerous representations, both of Assyrian and Egyptian harps, have been found; and they, the latter especially, argue not only great mechanical skill and considerable musical science, but the power of producing music which it is likely might have been considered pleasing and effective even by us Europeans of the nineteenth century. Not so with the Greeks, who never adopted the harp. The trigonon, an inferior harp, and the lyre, were in use among them; but, with a single possible exception, there is not a Greek monument extant including any representation of a harp. What sort of music, in our sense of the word, could have been got out of the lyre it is not difficult to imagine. But the music of the Greeks was altogether another art from ours. They, of course, originally received all their arts from nations older in civilization than themselves, and their aim and object would seem always to have been to simplify them. The same craving for what is called the chaste in art, which led the Greeks to the substitution of the lintel for the arch, and the repetition of the severe forms with which we are all so familiar for the intricate outlines and variegated surfaces of Asiatic architecture, would naturally induce the rejection, as barbarous, of an art so nearly akin to these latter—poliphonic or part-music. The lyre is not of Greek invention; it was known both in Assyria and Egypt. Of instruments known to us chiefly through representations, it is not extraordinary that we should have recovered little about the musical construction or methods of tuning. Mr. Carl Engel, to whose works on ancient music Mr. Hullah had more than once referred, has made some ingenious suggestions on this subject. He thinks that many ancient instruments were tuned to a scale of only five sounds; and his conjecture is supported by the fact that many do consist only of five, or twice or thrice five strings. The "instrument of ten strings" of our translation of the Psalms of David will of course come into everyone's recollection. Seven strings, the number found in some ancient instruments, might have been tuned very efficiently in the Greek order of *conjunct* tetrachords. No succession of so few sounds as the last could possibly be contrived out of which such a variety of agreeable melody can be got. The presence of the lower leading note gives it a great advantage over our scale, while the absence of the tritone makes it much easier to sing. Moreover, it includes the third from the tonic (as we should call it), which decides its mode as

major. A great number of popular tunes are contained within the compass of two conjunct Greek tetrachords, among them our National Anthem. The lecture was illustrated by a large number of drawings of ancient instruments, and some specimens of oriental reed pipes.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 3rd, 1867; The Earl of SHAFTESBURY, K.G., in the Chair.

The following candidates were proposed for election as members of the Society:—

Brown, Thomas P., 24, Surrey-street, Strand, W.C.
Despointes, F., 11, St. Luke's-road, Westbourne-park, W.
Jones, Sir Willoughby, Bart., Cranmer-hall, Fakenham.
Roe, Charles Wm., Padmore-villa, Sunny-bank, South Norwood, S., and 37, Moorgate-street, E.C.

The following candidates were balloted for, and duly elected members of the Society:—

Folliott, William, 12, Idmiston-villas, Forest-gate, S.E.
Lewis, R., 18, St. James's-street, S.W.
McCall, J., C.E., 137, Houndsditch, N.E.

The subject introduced for discussion was—

SUGGESTIONS FOR A MODE OF SUPPLYING CHEAP AND HEALTHY DWELLINGS FOR THE WORKING CLASSES, WITH SECURITY AND PROFIT TO THE INVESTOR.

By THOS. HAWKLEY, Esq., M.D., LOND.

Before describing the method of providing suitable dwellings for the working classes which I am desirous of submitting to your consideration, I will beg to premise, as briefly as possible, a few observations on what appear to me the faults of our system in dealing with the requirements of the poor, and I regret that the time usually allotted to communications of this kind will not allow me to refer much to the authorities and the exact data on which my argument is founded.

We know that a considerable portion of the community in our country suffers under the difficulties of poverty, difficulties connected with bad and to them expensive dwelling accommodation, dear and adulterated food, impure water, foul air, insufficient clothing, firing, and want of education. To the persons so circumstanced life is a struggle from birth to death. In the conflict, from 17 to 27 per cent. of their infants perish within the first few months of their introduction to a world to them so hard and cruel. The children who survive these first rude assaults grow up pale, weak, and old before they are young, so little do they see of the play and sunshine appropriate to infant years. Many die early of scrofula or consumption, or, if they become men and women, they die on an average at half the age of others, having in that time lived the life of drudges, amid the unwholesome and wretched conditions that support and propagate the long list of preventable diseases.

A careful study of the census tables under the heads of the occupations of the people gives a strong support to the belief that, while the educated and trained members of the community are as one only, the numbers of the uneducated and the ill-trained are as many, at least, as three; so that, in a population of 20 millions, there are three-fourths, or 15 millions, predisposed, for want of the protection and the aid afforded by education and training, to gravitate into that substratum of society—the poor, or the pauper class. We know that the numbers of the latter, or pauper class, are equal to 15th of the whole community; and, judging from the distress in the east of London and elsewhere whenever some unusual strain is put on the poorer population by pestilence, disturbed industry, or severe weather—(on the last occasion—the frost in January—in the east of London

alone, 100,000 sufferers were relieved); judging, as from the ascertained fact that, of every seven or eight deaths occurring in London, one takes place on the provided by charity; and again, from the enormous machinery employed to relieve poverty, which in the metropolis distributes some two millions sterling for the relief of the bodily wants of the poor, irrespective of the amounts employed in education and religion in the behalf, and independent, too, of the £900,000 and upwards expended from the poor-rates; judging from these evidences, there can be no doubt that, at least, three-fourth of the poor exist to every completed pauper. Six of those best qualified to judge believe that in the metropolis there are half a million of poor, struggling between pauperism and self-dependence.

If we ask what evil influences are at work to produce and maintain this large amount of misery and destitution in the midst of the richest and most humane people (judging by their charities) in the world, the reply must be that it proceeds from two principal sources: the first is ignorance, or the want of education and training which make men and women competent and valuable to their employers, in consequence of which the rewards of their labour—their wages—are much less than they might be, and the ignorance which leads them to adopt bad hygienic management, and to prepare their food badly and wastefully. The second great source of evil to them are the conditions so unfavourable to health in which they are surrounded, and to which their poverty leaves them helplessly—the crowded, unhealthy, and wretched character of the only dwellings they can get, with the deficient light, their bad drainage, and the decomposing filth within or around them—conditions which furnish the necessary elements for the germination, the growth, and the propagation of the preventable diseases, such as typhus, typhoid, relapsing and remittent fever, scrofula, measles, cholera, and, from the lowered vitality produced by such dwellings, scrofula and consumption.

It should be known by those whose happier state of life preserves them from these unwholesome conditions which act as fever-nests and hotbeds for nursing the preventable diseases, that the seeds of these diseases thus abundantly produced steal beyond the locality of their production, and enter the comfortable houses of the middle classes and the mansions of the rich, where, though they find fewer victims, they are wont to take more deadly influence on those they find, as if the constitutions unused to the destructive influence of poisonous agents felt them more than those constitutions which had established a degree of tolerance—just as it is found that chloroform is often more deadly to the healthy than the diseased. And surely, when we mourn the loss of some valuable life in the upper or middle classes, cut off by one of those diseases, which had its origin in poverty and indifference to the sanitary conditions of the poor, we may feel it to be like the stroke of an avenging Providence.

Thus we find that a variety of the most powerful arguments combine to demand—not only on the ground of prudence and foresight, but also on that of compassion, humanity, and of solemn responsibility before God, that we should remove these heavy burdens from the poor, and give to them a fair field for the fulfilment of their duties.

We have seen that, almost fabulous in amount as are the charities of England, and of the metropolis in particular; necessary and good in their way as are our workhouses, hospitals, asylums, and relief associations, after all they only *relieve* the evils of pauperism and destitution *after* the fact—they cannot and do not in any way come *before* and *prevent* those evils. Their increased number and extent are, in fact, a measure of the increased and increasing evil of pauperism, and their employment under a right system should be looked upon as a temporary palliative, while the true and really useful work of pauperism is getting into operation.

and producing its fruits. Every student of human nature knows that before a man can accept alms and loles, his self-respect and self-help are gone, and he is apt to become the careless, idle, servile, and hypocritical object so extensively produced by our workhouse system.

On the other hand, if we adopt a system that does not pauperize, but treats the poor man with respect, and simply makes it possible that the wages of his honest labour shall be able to command the decent and comfortable requirements of life—that his home may be bright and cheerful, and not so wretched that perforce he is driven to the public-house—that the health of himself and family is not so constantly oppressed by heaviness, angour, and weakness, that all hope and enterprise are taken out of him, and that, instead, he is able to look forward hopefully, and to be possessed of an incentive to progress—that his children can be educated and trained by means at his command, and that he is not obliged to leave them to run wild in the streets, to become thieves and vagabonds—then we may hope to find, year by year, that our poor rates are reduced in amount, our workhouses less and less occupied, the mortality and sickness much diminished, and the general prosperity and happiness increased.

In the laws of nature, all things work together for good, and nowhere do we find an example of a law designed to accomplish some useful end counteracting its intention by producing in its action some other evil. It is the same with really wise human laws; the only proof that they are so is to be found in the fact that they move harmoniously with the general good, and in repairing one injustice do not make another.

In the instance before us, we desire to relieve our suffering fellow-creatures from the oppression of diseases which afflict them ten times more than the rest of the community;* and we are anxious to know that the habitations they can afford to rent are fit for human beings to live in.

To obtain these results on one system of management,—that of *relief*—we expend in the metropolis alone, in all probability, at least three millions per annum, independently of the immense sums given in private charity; but we have made no advance. The *Times*, in a leading article in last January, says, "To any one who was ignorant of the organization of the metropolis, it would seem as if there was no provision whatever for the relief of the London poor."

Dr. Farr, in the supplement to the 25th annual report of the Registrar-General, 1864, says that the loss of life in 30 large town districts, comprising St. Giles's, East London, St. George's-in-the-East, St. Saviour's, St. Olave's, and St. George's, Southwark, and others mentioned, equalled on an average in the ten years, 1851—60, 71,194 annually; but the proper number for the same population in a healthy district would have been only 33,459. There was consequently in these 30 districts an annual sacrifice of life amounting to 32,735; which, as Dr. Farr says, "may be justly ascribed to the unfavourable sanitary conditions in which the people live and die."

In the same supplement, Dr. Farr says that at the age from 45 to 55, the mortality of London men is double that of men in the healthy districts.

These impressive facts enable us to understand the enormous pecuniary cost sustained in England by the loss of labour and the sickness from preventable diseases. That cost has been estimated for England and Wales, to be equivalent to over thirty-two millions sterling per annum, and for the metropolis alone to nearly five millions per annum.

* Of upwards of 18,000 deaths from cholera which occurred in London, in 1849, it was found that they were in the following relative proportions:—

Of the gentry	2·6 per cent.
" tradesmen	15·7 "
" mechanics	81·7 "

By another system, that of prevention, by removing the causes of preventable disease and by education, we may find that we not only attain our ends and cure the destitution and misery that are so wide spread and so injurious to all classes, but we may find that the system is self-supporting, and that in this instance as in others, *the right method is inexpensive, and the wrong one very costly.*

The great evil of unfit and insufficient habitations for the poor and labouring classes, has been greatly on the increase of late years, and now, from the railways advancing their termini into the centre of the metropolis, the formation of metropolitan railways, and the taking up new ground for other public improvements, as for the building of the law courts, the difficulties have been immensely increased. Within the last quarter of a century, several associations and individuals actuated by a noble philanthropy have stood forward to do battle with this great cause of wrong and oppression.

The first on the list is the Metropolitan Association for improving the Dwellings of the Industrial Classes, offices, 19, Coleman-street, City. This institution was founded in 1841. From its last report we learn that it has ten metropolitan establishments, which lodge a population of 2,572 persons. The average mortality of this population was a fraction over 17 per thousand. The dividend for distribution to the shareholders after paying all demands and providing for all contingencies, was 3½ per cent.

The second is the Association for Improving the Condition of the Labouring Classes; offices, 21 and 22, Exeter Hall. This was founded in 1844, and has pursued a very active and useful career. It now lodges about 1,625 persons in eight London establishments. The mortality in this population for the last four years, like the former, has been a fraction over 17 per thousand. The dividend divisible as net profit on the dwellings (separating the baths and wash-houses from the calculation) is 5 per cent.

The third association is the London Labourers' Dwellings Society; offices, 3, Charlotte-row, Mansion-house. This has paid 5 per cent. from its formation, after setting apart a sum sufficient to provide for the redemption of the leasehold property. Particulars are not given in the report received of the population or rate of mortality.

The fourth is the Improved Industrial Dwellings Company, limited; offices, Carpenters' Hall, London Wall. From the experience of its working up to the present time, the directors believe that a minimum dividend of 5 per cent. per annum may be relied upon.

The fifth are the houses erected by Mr. W. E. Hilliard, in one of the worst districts in London, that of Shadwell. Mr. Hilliard first built twenty houses on this property, on the general plan of the model cottages of the late Prince Consort. Each house containing four dwellings, cost £487 to build. After an allowance for ground rent and all other expenses, the return has yielded a clear 6 per cent. per annum; and so satisfactory were the whole results that Mr. Hilliard determined to build more of these houses sufficient to accommodate 108 families.

There are also the model buildings erected by the late Prince Consort, those of the great Peabody benefaction, and others by Miss Burdett Coutts, all of which have been erected with less regard to any commercial success than to the purely benevolent one, and therefore they do not furnish the same kind of experience on that head. But from all, we learn the same reports of improved health and morals, and of diminished mortality.

Mr. Glover, the Superintending Medical Inspector of the General Board of Health, in his report, dated January 20th, 1856, says:—"Some of these (Mr. Hilliard's) houses have been occupied nearly three years, and the average population during that period has been 450. Among this number of inhabitants, congregated in one of the worst localities of the metropolis, a large portion of them being children, it is gratifying to find that there

has been a considerable diminution, if not an almost total absence, of epidemic* disease. There has not been a single death from cholera or diarrhoea in any of the houses." Again, he says:—"The erection of these Albert-cottages, provided with arrangements essential to health, comfort, and morals, is producing the happiest results in the neighbourhood. Tenants have become sensible of the discomfort and evils of their unwholesome dwellings."

Mr. Henry Roberts,† speaking of the model lodgings and dwellings generally, says:—"But not only has the improvement in the physical condition of the occupants of these houses answered the most sanguine expectations of their founders, but it is still more gratifying to know that moral improvement has been made. The temperate have become sober, and the disorderly well-conducted, since their residence in these healthful and peaceful abodes. No charge of crime, nor complaint of disturbance, has been lodged at any police-station against a resident in these dwellings. The neighbourhood in which many of the houses are situated has also participated in their ameliorating influence. They appear to act as silent monitors, reproving disorder and encouraging cleanliness and propriety."

The superintendent of one of the establishments says:—"The nocturnal uproars in the adjoining streets, which constantly disturbed the inmates when first the houses were opened, gradually diminished, and finally ceased altogether."

The diminution in the rate of mortality in these improved dwellings is much greater than might have been expected, when we consider that the real difference is not as 17 to 24 (the ordinary general rate of the metropolis), but, seeing that the diminished rate has occurred amidst the most unhealthy parts of the town, the difference cannot be less than that of 17 to 33. This saving of life implies much. It tells us of increased fitness for work and exertion, of hours and days saved from suffering and from loss.

"Dread to the poor the least suspense of health,
Their hands their friends, their labour all their wealth.
Let the wheel rest from toll a single sun,
And all the humble clockwork is undone.
The custom lost, the drain upon the hoard,
The debt that sweeps the fragment from the board.
How mark the hunger round thee, and be brave!
Foresee thy orphans, and not fear the grave!"

It tells of much pain and anguish prevented, of many children preserved to fulfil the purposes of their being; of parents saved to be their guardians and protectors! It tells of a small portion saved of that four or five millions of money wasted in the metropolis by the existence of so much preventible disease. God speed therefore the noble work of the philanthropists and patriots who manage these invaluable institutions; they merit the gratitude of their country as the pioneers of the most pressing and important reform affecting the welfare of the bulk of the people; and not only for what they have effected, but for what they have taught us.

Unfortunately, great and valuable as the amount of work done by them is, it is but a very small portion of that which remains. There are, possibly, eight or ten thousand poor well lodged in these improved dwellings; but the lowest estimate indicates that improved dwellings are wanted for 200,000 persons at least, and it is not likely that these associations will be able either to provide for so many, or to provide them on a scale sufficiently cheap for the poor, and yet sufficiently remunerative to the public to attract the investment of money for the purpose. The Prince Consort said to Mr. Henry Roberts, the honorary architect of the Association for Improving the Condition of the Labouring Classes, "Mr. Roberts, unless we can get seven or eight per cent., we shall not succeed in inducing builders to invest their capital in such houses." This observation exactly hits

the truth; as a commercial speculation the work would not spread and be successful with only five or six per cent. returns.

Another obstacle that opposes their success, is the difficulty of obtaining the property which, by its unfitness, has become a source of evil, and which it is necessary to improve or to clear away, and replace by suitable dwellings. Such property is often possessed by persons who have no regard for their fellow-men, and consider only the money to be screwed out of them, by providing them with lodgings which cost little or nothing to keep in order, and for which they obtain the same rent as those supplied by the associations, with every comfort. By this unprincipled course, such property may pay from 20 to 30 per cent., and by the humane and honest one only 5 or 6. It is not wonderful, therefore, that great opposition is often experienced in effecting the reforms necessary.

The societies have also experienced difficulties, for example, in being able to obtain only one side of a street, when the improvements would be impracticable without possessing both sides. Sometimes the property was in Chancery; or it was held by a number of persons; or unprincipled solicitors would put in every obstruction to proof of title and of sale, in order to increase costs. Sometimes the property was entailed, and burdened with a complication of claims; or part was held by some one abroad, or supposed to be dead; or the societies were met by disreputable owners with an almost vindictive demand for such outrageous prices, as made all dealing hopeless.

The Society for the Improvement of the Condition of the Labouring Classes has, in these ways, had to pay heavily for some of the property they purchased. The consequence is that the Streatham-street establishment costs £38 a head of population; the Portpool-lane, £64 a head; and the George-street lodging, £61 a head. On these conditions it is not likely that dwellings for the poor can be built to pay the 7 or 8 per cent. necessary to attract investors. Notwithstanding, this association has been able to supply some of its single rooms to the poor at as low a rental as 1s. 6d. a week, with the other results named.

Mr. McCullagh Torrens, the member for Finsbury, has just carried through its second reading a Bill, the intention of which it is impossible to praise too highly; the only questions concerning it are whether the mode it prescribes for enforcing the improvement or the rebuilding of the condemned property might be simplified and made more effectual; and whether the mode of providing the means to carry out the work might not be placed on a larger and more expansive basis.

The mode of acquiring the property, or of enforcing its improvement, under Mr. Torrens's Bill, would appear to be unnecessarily indirect and troublesome. There is

1st. The report of the officer of health, who is a parish officer, and who, failing to initiate proceedings may be called upon to do so by four householders.

2nd. The officer of health has to deliver copies of his Report to the clerk of local authority and to the clerk of Peace.

3rd. The clerk of local authority is to lay his report before the council.

4th. The clerk of the peace is to do the same before the grand jury, who will make a presentment.

5th. The clerk of the peace is to send a certified copy of his presentment from the grand jury to the clerk of the local authority.

6th. The local authority thus advised of the grand jury's presentment, prepares plans and specifications of the required works, and the clerk gives notice to the owner of the property of the grand jury's presentment.

7th. Against this presentment the owner may appeal within 14 days.

8th. Or the owner may within three calendar months elect to do the work required, or to require the local authority to do the work, and to use the property.

* Epidemic diseases are among the preventible class.

† Vide "The Physical Condition of the Labouring Classes," by Henry Roberts, F.S.A., 21, Exeter Hall.

9th. In the latter case, if the parties do not agree between themselves as to the bargain, the local authority having delivered to the owner the valuation made by two able practical surveyors, then, if within a month of the receipt of such valuation the owner have not signified his intention to accept it, the local authority shall pay in the amount of the tender in the manner prescribed by the Land Clauses Act of 1845, and the local authority shall be at liberty to proceed with the work of improvement or demolition, as the requirements of the case may be.

10th. The property thus acquired by the local authority shall be held by it in trust for the purpose of—

a. The providing the labouring classes with suitable dwellings, by the construction of new ones, or the improvement of existing ones.

b. The opening out of closed, or partially closed, alleys or courts.

11th. Lastly, the local authority shall not possess this trust on any given property longer than for 7 years, and if during that 7 years it fails to sell, exchange, lease, or otherwise dispose of it, at the end of that time it shall revert to the Crown in the same manner as if it were land belonging to a corporation which had no power to hold the same.

Now in a work of this kind, in which philanthropy and high principle have to take the place of personal interests, it is very desirable that the persons undertaking the trouble should be exposed to as few vexations and prolonged contests as possible; and it would also seem necessary to have the business transacted by persons and officers in a position as regards parish interests independent and impartial. The persons who most interest themselves in parish and vestry management are often personally interested in property of which the general good demands the reform.

1. The mode of acquiring the condemned property or of enforcing the improvement of it, would be rendered much more easy and effective by leaving the associations who would effect the work to obtain information of unfit premises or localities from all informants, not of course excluding the officer of health, but rather attaching the greatest importance to his information.

2. After the information received, the association should delegate its own officer to visit the place, who with the assistance of the officer of health would get up the accurate facts, and then report to his Board.

3. The association, having concluded that the case demands interference, draws up its statement, estimates, cost, &c., and then,

4. Sends a copy of its presentment to the owner of the property, and another to the Government officer appointed to control the associations.

5. The government controller not intervening, and thereby assenting to the justice of the presentment, the association next endeavours to make terms with the owner of the property for the fulfilment of the requisite improvement, and the owner objecting to come into the undertaking, the association then cites him to appear before the justice of the peace, or the tribunal appointed to try such cases, and thus all dispute might be summarily settled according to the rules of law and equity, in conformity with the Lands Clauses Act.

This method would probably save trouble and expense to all parties. It would require no parish rate to be imposed for carrying it out, and all the funds for every expense would form a part of the outlay of the associations, as they now do. The work would be pursued with a single eye to the public good without the impediments of local influence; and this mode would be specially advantageous as obviating the necessity of selling the property within seven years, and so avoiding the risk of its falling back into the bad state and management of its previous owner.

The following conditions are laid down as necessary:—

1. The removal of all the existing foci of disease, and

the unsuitable poor dwellings, and their replacement by healthy ones appropriate for artisans and labourers. The improvement of those dwellings that do not require demolition, and the opening out closed courts and confined spaces.*

2. That the rent to be paid by the occupiers of the proposed dwellings shall be on a scale adapted to the requirements of the humblest artisan or labourer, and on the other hand that the net profits on the general undertaking, shall secure a minimum five per cent. dividend on the capital paid up.

The first condition will require for its fulfilment a large sum of money. If Mr. Torrens' estimate of one million sterling for 35,000 habitations be correct, which is about £28 10s. a head, it must require at least seven millions to build dwellings for the smallest number believed to require them? Does it not seem better that the supply of means should be of an elastic character, capable of accommodating itself to the requirements, whatever they may prove to be, rather than to shut up the work in a defined and inadequate sum? But as the work will not pay the highest interest necessary to attract this capital as an ordinary adventure, (the 7 or 8 per cent. laid down by the Prince Consort) what is required is to make it so desirable that some of the immense wealth of this country, waiting for investment, may be attracted to it. It is presumed that if the government would guarantee a minimum of 4 per cent. interest on such investments, the object would be immediately attained. To the public desiring a safe investment for their money it would be a great boon, for their property would be as safe as in Consols; and while tolerably certain to receive an interest of not less than 5 per cent., the government would be responsible for the minimum of 4 per cent. The debenture certificates of the associations would be easily negotiable; and there can be no doubt that, in these days of commercial imposture and dishonesty, the demand for such a safe and desirable mode of investment would be greater than the supply. But what objections might the government be supposed to interpose? As to want of precedent, it may be replied that in India, the government has thought fit to guarantee the railways. In England, if there be no precedent, it may be replied that in this instance, the claims for the boon demanded are so important and peculiar, that compliance with them is not likely to be dragged into a precedent for any object. The importance consists, as before-mentioned, in its being necessary to prevent death, disease, and misery, to an immense portion of the community, and damaged health and prosperity to all. The peculiarity is this, that in granting the boon the government accepts no risk. Every shilling of the money subscribed by the public would be invested in houses and land, the natural tendency of which is to increase in value, and which in themselves constitute the safest property in existence. The property would be managed by associations of gentlemen undertaking the work from the highest and most disinterested motives; government officers would be associated, who would be responsible to the government for the probity and the prudence of the management, and lastly, a net profit on the undertaking of not less than 5 per cent. per annum, would be insured by the following plans to be discussed under the second condition.

This second condition requires that the dwellings should be let at a rent that the humblest labourer can pay, and yet that the whole undertaking should return a profit of at least five per cent. after satisfying all claims.

Until the working classes become more prosperous by a diminution in the oppression and misery caused by

* It is not supposed or intended that the whole of condemned London is to be pulled down and rebuilt at the same time. The associations would take care that everywhere the convenience of the poor should be studied, and the work, though commenced on an extensive and comprehensive scale, would be so diffused and managed, that from the first increased instead of diminished accommodation would be provided.

preventible disease, it would seem that a very large majority of them, at the present rents, can afford to pay for one room only. Even in the rich parish of St. George's, Hanover-square, we learn from Professor Kerr's paper, read before the Institute of British Architects, that of 1,500 abodes of the poor visited in that parish, it was found that 8½ per cent. of the families only had three rooms, 28½ per cent. had two rooms, and 63 persons had one room only. In the poor parishes the inability to pay rent is greater still; and it would appear that the provision should be, that the rooms being built in compliance with the requirements of health and comfort, comprising the proper allowance of light, ventilation, water-supply, and other conveniences, the rent per room should be from 1s. 6d. to 2s. and 2s. 6d. a week. This scale, it is believed, would provide for the wants of the poorest individual or family; and there can be no doubt, with the improving action of these dwellings on the health and morals of their occupants, that very soon each family would be able to pay for three or four rooms, and in the first instance for two.

The other feature of this second condition—that the undertakings should return a clear profit of five per cent. at least on capital, is made clearly practicable by the following features of the plan:—

1st. The purchase of the property to be by *compulsory sale* and reference to an *equitable tribunal*. By this means extortionate prices would be saved, and the greatest difficulty in building for the poor cheaply would be avoided.

2nd. Advantage would be taken of the valuable experience obtained by the pioneers on the road, both in the form and arrangement of such buildings and in the materials used in their construction. For example, the architect of Mr. Alderman Waterlow's buildings (Mr. Allen) discovered a material which combines cheapness, durability, ornament, and economy of labour, and this has enabled him to erect the buildings for "The Improved Industrial Dwellings Company" at much less than the ordinary cost. Probably substitutes for brick and stone may be made cheaply on the same principle, wherever shingle can be had without much cost.

It may be found advantageous to vary the form and arrangement of the buildings according to the requirements of the neighbourhood; and it is suggested that not only would it be found profitable in some situations to make the basements into shops, as has been done in Mr. Waterlow's houses, but also that in others it might be found to pay well to convert the flat solid roof into workshops and warehouses for the use of the tradesmen in the neighbourhood, who would be able to pay a good rent for them, and so lighten the rental of the dwellings.

The writer believes that a time is coming when the refuse of houses, now so mismanaged that it is the principal cause of preventible diseases, and is also a great expense to remove—will, by good management, become a source of profit, and, at the same time, by saving the water now used in washing it into the sea, that water may then be supplied by the water companies in a continuous supply, so that the expense of cisterns and other apparatus for storing water may be done away with.

These instances are merely given as examples of the many ways in which expense may be saved in building these dwellings, and, at the same time, improving their healthfulness and comfort, and, taken in connexion with the experience of the society of which Lord Shaftesbury is the chief, that of which Lord Stanley and Alderman Waterlow are chiefs, that of Mr. Hilliard, and the London Labourers' Dwelling Society, it may be confidently affirmed that the conditions laid down for fulfilling all the requirements of these dwellings may be perfectly realised, and a profit of at least 5 per cent. secured, after satisfying all charges and contingencies. Thus the Government is called upon to give only the

agis of its protection and security to this great nation; and all-important work; and while accepting no risk or expense, it would confer immense benefits on the whole community as regards its prosperity, health, and morals.

In conclusion, allow me, very briefly, to sum up the positions I wish to establish. They are:—

1. That a very considerable portion of the population in this country is exposed to the risks and penalties of preventible disease, and in a degree most unequal and unjust as to the rest of the community. Also that a portion of the population referred to is constituted of the persons throughout the land who, from their ignorance and their poverty, are quite incapable of rectifying their position without the assistance of their less-oppressed fellow-countrymen.

2. That Government and society, having always recognised the duty of assistance, have generally adopted one of two systems for its fulfilment, both of which act only with the results and effects of the evils referred to, and leave their fountain or causes unopposed. The two systems are either that of *relief*, as of visiting the sick, feeding the hungry, and clothing the naked; or that of *repression*, as by making parochial relief and workhouse management so hard and painful that none but the driven to a last resource, or whose spirit had been broken by previous experiences of their degrading influence, would apply for their aid. Of the same repressing character is an enactment which would drive our poor wretches from over-crowded lodgings, without at the same time providing better ones.

3. That these systems of dealing with the evils referred to are very costly, it having been calculated that the preventible diseases involve a loss to the country of over thirty millions sterling a year, and the relief of their destructive effects cannot be less than another cost of fifteen millions per annum.

4. That the system of *prevention* is inexpensive, it not only diminishes more and more the production of the evils referred to, but the machinery employed in the work is, for the most part, self-supporting. Its scope of action is not the charity that gives money to relieve suffering, excellent and necessary as that is where it suffering exists; but it is the higher and broader charity which recognises in every human form a nature precious as our own in God's sight, and which would shrink from moulding that nature into the pitiable and degraded form of the pauper, but rather would treat it with respect, and seek to elevate it, by making it possible that the wages of honest labour may be able to procure the requirements of life under the conditions of health and decency.

5. That the want of a sufficient number of healthy dwellings, at a rental practicable to artisans and labourers, having been shown to be the chief cause of these evils, the principal work of the preventive system is to supply them.

6. That the associations now at work for this purpose afford a ready, convenient, and inexpensive machinery for carrying out the object to a successful issue. The results of their operations as seen in the improved prosperity, character, and in the diminished mortality of the population for whom they have found healthy dwellings, prove the correctness of their method; while the independence of the plan of parish rates, parish interference, and all new burdens, recommends it for simplicity and efficiency.

7. That this machinery, to be successful, requires two helps from Government:—

a. The compulsory power of purchasing property which can be proved to be a public nuisance, and a source of disease and immorality, but which the owner thereof neglects or refuses to improve.

b. The grant of a guarantee by the Government to the public investing in this useful and patriotic work, to the effect that a minimum interest of 4 per cent. per annum shall be its perpetual condition.

The Government has long been an anxious one to the

riter, who, as physician to one of our public infirmaries for consumption, has had great practical experience of the destructive and degrading influences on body and mind of the unfit dwellings of the labouring classes, and the hail with thankfulness the good step taken by Mr. McCullagh Torrens. He hopes, however, that the suggestions herein offered may receive a thoughtful and serious consideration, with a view to the modification of Mr. Torrens' Bill in order to meet them.

DISCUSSION.

Mr. EDWIN CHADWICK, C.B., said that, at a time when large extensions were contemplated of healthy homes for the labouring classes, it was proper to call attention to the fact that the common constructions were not healthy to the extent that was practicable. The improvements in the removal of the sewage, and of the decaying animal and vegetable matter, were now pretty well understood, and sometimes sufficiently well accomplished, with the result of the reduction of the sickness and death-rates by one-third in common constructions. But another important desideratum was to prevent damp and foul deposit, and the retention of noxious miasma, and to ensure complete dryness and purity in the common wall. On occasions of extraordinary epidemics, all experience showed how long fetid and noxious smells were retained by absorbent walls. In cases where the authorities had been prevented by obstinate landlords, or other causes, from properly cleansing and scraping such walls, when, after a time, new inmates occupied the premises, it was observed that, in the houses that had been successfully defended against the wall cleansing, and in those alone, fever had broken out again amongst the new occupiers, thus demonstrating the deleterious influence of the foul absorbent walls. In hospitals, where the cleansing of the walls had been too long neglected, instances occurred where every man engaged in scraping and cleansing them had been made ill. With such experience it had become a sanitary rule of hospital construction that the walls should be constructed with a non-absorbent and readily washable surface, and this sanitary rule ought to be universal as a principle of construction for common habitations. The common lath-and-plaster constructions—the laths which rotted, and paper which harboured vermin—were unwholesome. The common wall constructions were, moreover, objectionable from their tendency to absorb damp. Every common brick in lower-class dwellings absorbed a pound of water, and thus a two-storied cottage, when completely saturated with moisture, would absorb as much as six hundred gallons. To protect the inmates from driving wet, expensive slate coverings were often resorted to. But it was not alone the driving wet, but the wet rising from the ground, carried up by capillary attraction, in these walls of absorbent, spongy stone, as well as of brick, that had to be guarded against. The evaporation of the excessive wet lowered temperature, and the chills thus caused frequently induced the use of stimulants. Damp lowered the bodily condition, and rendered it more susceptible to disease. Numerous cases of rheumatism, so common in the country, were due to the damp of the walls of the cottages in which the people lived rather than to the wet of the fields in which they worked. But the evil was not confined to the lower class of houses. The damp material, of which better class houses were constructed, rendered them unsafe to inhabit for nine or twelve months after their construction, when they had undergone some degree of drying. A row of newly-constructed middle-class houses was sure to be the seat of an extra amount of sickness immediately after their first occupation, as medical men were well aware. For the prevention of this species of evil, he had some time ago imagined and endeavoured to promote wall constructions with hollow hard-burnt non-absorbent vitreous bricks. Houses might thus be built so that they might be safely occupied at

once. Walls of the common material, though cheap to construct, were certainly dear to use. But if the hollow bricks were made of a large size, hollow pots in fact, they were cheaper to construct. The obstacles to their introduction had been that they required special and large machinery for their production, and an alteration of trade habits of construction. Plans and estimates had been prepared at his instance, by Mr. Robert Rawlinson, and these having been submitted to an eminent builder, his estimates showed an economy of 20 per cent. On the builder being asked whether this form of construction was practicable, he had said "Yes," but when asked, "Will you adopt them?" he had said, "No, I will not; because this large form of brick will require two hands to use them, and my men will strike when I attempt to introduce it. Thus there will be a great deal of trouble in altering the present practice and habits of construction; and when I have done it all, and proved the economy of the work, other builders will profit by my experience, and build as cheaply as myself. I shall have all the trouble of the change, and I shall have no profit from it, so I will not undertake it." Other large firms took the same view, and so improvement was stopped. Hollow bricks of the common form, and somewhat less absorbent, had been got into occasional use, but a complete reform of the present deleterious principles of construction had yet to be accomplished. The late Capt. Fowke had directed his attention to some forms of concrete, as an improvement upon the common brick construction, and had had some preliminary trials made with concrete made of Portland cement and of Scott's cement, which showed that the concrete was not from one-third to one-fifth so absorbent as common brick, and might receive an almost perfectly non-absorbent and washable interior facing, which was a great desideratum. The material, sand or gravel, or breakable stone, or the slag of furnaces, was procurable everywhere. There was a lodge of concrete, and walling of concrete, at the South Kensington Museum. He had seen some cottages on the Marquis of Salisbury's estate at Hatfield, where he had built a church and a farmery, and where a park had been walled with concrete. The occupiers of the cottages and the farmer attested the dryness of the walling, which was the essential sanitary point, and as to the economical question, the cost was about half that of brickwork. In cottage constructions, half the expense was the walling and other parts now made of brickwork. Now, if this half was reduced one-half in cost, if $5\frac{1}{2}$ per cent. were gained by the common constructions, seven per cent. or more appeared to be attainable by this new form of construction, almost anywhere, even without new or costly machinery for "pot" manufacture, for which we should have to wait. He considered that trial works of new materials were now a great desideratum.

Mr. HAWES confessed, when he read the title of the paper, he expected to hear something new about the cost and construction of cottages, whereas the author had not spoken of any improved modes of construction other than those practised with the greatest success by Alderman Waterlow. The principal point on which stress was laid was, that the Government should guarantee a certain minimum rate of interest on any funds which the public might provide for these purposes; and that proposition had been brought forward by the author of the paper as an amendment upon the bill of Mr. McCullagh Torrens, the principle of which was, that Government should lend money upon the security of the buildings, when erected, at a low rate of interest. There was a great distinction between the two plans, and he thought Mr. Torrens's plan was the best; for by the system of a guarantee, all security for the proper management of the property was lost, whereas, in the case of a loan, this was not so. It was to improved construction and management that they must look for success. The mere obtaining of money was of little use, unless as a means of carrying out really well-digested and well-

considered plans. Dr. Hawkesley's paper repeated, in language of a very attractive character, but still repeated, he thought with very considerable exaggeration, a great many of those statements which were frequently indulged in in the discussion of this subject. They were told that the average rate of mortality in the poor districts was 33 per 1,000; but, in considering this question, was it fair to take the maximum rate of mortality and then compare it with that in the model lodging-houses, which were occupied by the best sort of people of the class referred to—by the most industrious and cleanly as well as those with the smallest families? For it was only the better classes of workmen who could take advantage of these model dwellings. It was, therefore, an exaggeration to infer, from the fact of the mortality in these lodging-houses being only 17 per thousand, that, if such dwellings became general, the whole mortality would be reduced from 33 to 17 per thousand. As to the obtaining of capital for the erection of such dwellings, there was no doubt that, unless they could be made a profitable investment, it was useless to attempt it on a large scale. The subject was too vast to be treated as a matter of philanthropy, or otherwise than as a purely commercial question. As soon as it could be shown that good profit would result, there would be plenty of money forthcoming; but here was the difficulty. With regard to the proposition of Mr. McCullagh Torrens, he (Mr. Hawes) was not entirely an advocate for that Bill. He thought that which was prepared by the Social Science Association was superior to it. But in both Bills the great object was directed not only to providing buildings of a superior class, but also to destroying the bad buildings which now existed, and which were at the present time the seats of disease and crime. There were thus two objects to be attained. They might say to the public—"Help us, not only for the sake of the profit you will derive from the investment of your capital, but because such investment well-directed will materially reduce the rates which you pay annually, and which are owing to the presence of all this vice and misery." On such grounds as these they might fairly ask Government to lend money on good security, and they might obtain the money at the lowest rate of interest, making the Government mortgagees of the property so created. On no other condition, he thought, had they any more right to go to Government for help than had any other commercial enterprise. But could they get from Government assistance enough? He contended, if the Government lent as much money as it could upon the security of the buildings, unless the remainder of the capital would pay more than five per cent., they would not get the other half from the public. Suppose they required a capital of two millions, they might borrow one million from the Government and obtain another from the public; on the moiety advanced by Government they would pay—say 3½ per cent.—but they must make sure they could pay more than five per cent. on the other half before they could get it. They were told that 200,000 people were required to be lodged, and that the present accommodation in model dwellings extended to only 8,000 or 10,000. The implied inference was, that they at present lodged 8,000 or 10,000 adults, but this number included adults and children too; they had not, probably, more than 1,000 families housed in these places; moreover, accommodation was required for many more than 200,000—something like a million—if the question were fully set with. His friend Mr. Chadwick had spoken about modes of construction, but he would not follow him into those details, for he thought the builders of the metropolis might safely be trusted to find out the best way of building houses cheaply. He believed if concrete was really better than bricks they would have used it before. There was a limit to which concrete could be successfully used—beyond this point they must, of necessity, introduce bricks; and no men knew better than the great London building contractors where the economy of the one material ended and of the other began. No doubt

certain qualities of bricks would absorb a considerable quantity of water if they were saturated by being immersed in it, but it could not be imagined that bricks in the ordinary position on the surface of a wall would absorb a pound of water by exposure to rain. That, one of those exaggerated statements which really did more harm than good. All exaggeration retarded rather than promoted the progress of sound principles with regard to this question, so beset as it was by practical and substantial difficulties.

Mr. W. E. Newton said that past experience on this subject proved the accuracy of the remarks of the Prince Consort when he said, if they did not succeed in making these dwellings pay a good interest it would be impossible to meet the immense demand that had been made for them. The philanthropic societies of which he had heard had no doubt done a great deal of good; they had inaugurated a better class of dwellings, and even how the thing might be done; but they were always way behind what was required. He might say many people when he said he thought the philanthropic societies had done wrong in endeavouring to give the working classes too many luxuries, which they did not require, and did not ask for; the consequence was that dwellings cost a great deal more than they need be done, and it followed that too high a rent must be charged. It was well known that the tenants of the houses built by these societies were not of the class which most stood in need of aid. They were those of the working classes, and formed but a small fraction of the population. Mr. Newton then proceeded to give some details of houses for the working classes which he is now engaged in constructing in Paris for the Emperor. Those houses were to be four in number, and several were already finished. They consisted of double houses, each containing apartments for six families, each family having a living room, bed room, kitchen, and separate water closet; with separate water supply for culinary and sanitary purposes. In the original plans submitted by him (Mr. Newton) to the Emperor and Empress, his Majesty made some modifications, sketching them on paper himself; and the houses were being erected according to the plans thus amended by the Emperor. There were cellars in the basements, and the cost of each of these double houses, capable of accommodating six families each, was without the cellars, £480, and with the cellars £530 per pair. Mr. Hawes had spoken slightly of concrete, but he could tell that gentleman that the houses were built of concrete almost entirely; and he could point them to houses he had built at Norwood, in which the entire walls, floors, and roofs, were of concrete. He had even succeeded in laying a roof, of 16 feet span and 36 feet long, not more than three inches thick of concrete. He thought that considerable economy resulted from the use of this material, as he calculated the cost was less than half what it would be if brick or stone were used. With regard to the houses in Paris, he wished to state that he started with the idea of not employing skilled labour in their construction, as that would have added very much to their cost. Acting upon that idea, labourers on the boulevards, who were willing to work, were employed to mix the concrete and fill it into the moulds at such wages as 2½ francs per day. The operations were carried on in four houses at a time, and the walls of each were raised 18 inches or two feet per day by filling concrete into a mould fitted for the purpose, into which the concrete was shovelled, and when a piece was dry, the mould was raised and the operation repeated.

The CHAIRMAN inquired what was the thickness of the concrete walls as compared with brick walls?

Mr. Newton replied, he should not object to trust a concrete wall one-third less in thickness than one of brick. He spoke of actual construction he had carried out. He had built a garden wall 100 feet long, 9 feet high, and 9 inches thick, entirely of concrete, and it stood perfectly well. He would not hesitate to carry

up concrete walls of houses 9 inches thick and 25 feet in height.

Mr. GEORGE CRUTKSHANK said, having given some attention to this subject for the last half-century, he had arrived at the conclusion which he had expressed as one of a deputation to Lord Derby—that, in order to remedy the great evils which had been described, it was necessary to rebuild a large part of this metropolis. His plan for doing this—which would appear in a little pamphlet shortly to be published—was that streets of houses should be built with shops below in each house, so that the street itself should form a market, from which every commodity required by the inhabitants could readily be procured. He regarded fire-proof staircases as a matter of paramount importance in dwellings for a large number of families. His plan was to have double houses, with a fire-proof staircase in the centre common to both; and he would have the rooms of such a size as to admit of thorough ventilation. A plot of ground in the City-road had been offered to him, and the only thing he wanted was the capital with which to commence building. The present model lodging-houses were good as far as they went, but they did not answer the purposes of the general community of the working classes. The idea of some persons seemed to be to build houses in which both the better and the lower classes of artisans might live. That he believed was impracticable, from the simple fact that the more respectable people would not live in the same houses with those whose habits were such as to render residential association with them impossible. The only plan was to provide separate accommodation for the respectable and well-conducted people, and that would make more room for the others. He was strongly in favour of compulsory measures being employed for compelling the owners of houses inhabited by the poor to have them well cleansed and properly ventilated. He need hardly say that in the plan he hoped to be able to carry out he had no desire for any profit to himself, but only to benefit the community.

Mr. NEWTON added that the houses he had built in Paris were constructed fire-proof, so that if a fire occurred in one apartment it could not communicate to another.

Mr. G. B. GALLOWAY said he believed that concrete was the best and cheapest material, but he would combine with it a kind of skeleton framework, which would be filled up with concrete, and thus form the house. On each floor he proposed to have four rooms, a living-room, two bed-rooms, and a kitchen, scullery, and all necessary appendages. Then he would have a bell to each floor, and have the name of the occupant on the handle, and he believed, with due regard to economy, each floor would not cost more than £120, and could be fairly let for £8 per annum. He considered it a national disgrace that no Englishman should have followed the example of George Peabody, though there were some equally wealthy who were content to express their sympathy only with the working classes, but did nothing of a practical character. He suggested that all real philanthropists should come forward and subscribe to a national fund, and then it would be very easy to secure the best plans for erecting suitable and healthy dwellings for the working classes.

Mr. BOTLY drew attention to one important point as affecting the healthy character of dwellings, that they should, as nearly as possible, face the south, and not the east or north.

Mr. R. N. PHILIPS, M.P., said one of the great difficulties in the way of providing better accommodation for the working classes was how to remove the present buildings, which were not fit for human habitation. They all knew that the rights of private property must be maintained, but where private property derived a benefit from that which was detrimental to the interests of society at large, it ought to give way. Mr. McCullagh Torrens's Bill had been mentioned, and in a great measure he cordially approved of its provisions, but he would hardly

go the length of raising money from the ratepayers to pay for the improvements. He was one of those who believed that if this property, which was dangerous to public health, were only destroyed, architects and builders would come forward at once and replace it with proper buildings. It was found in the manufacturing districts in the north that the only way to secure intelligent and respectable workpeople was to provide proper accommodation for them in the neighbourhood of their labour, and he believed that the same principle would be found to answer in London. If a considerable space of ground were cleared in the neighbourhood of any large works, there would be no lack of capital to build new dwellings for the working population, for the simple reason that they would be sure to be remunerative.

Mr. ROBINSON thought the effect of Mr. McCullagh Torrens's Bill would be rather to reward the owners of property in a bad condition for neglecting it than to inflict any loss upon them in consequence. By the provisions of the Bill, the owner could compel the Government to become the purchasers of his houses or property, and he did not see how they could provide for giving him less than the value of it as decided by the ordinary tribunals. Another proposal was that Government should purchase the equitable rights, but the great difficulty would be to ascertain what these were. He believed that the great objection to most of the philanthropic efforts in this direction was, that they put too strict a limit on themselves as to the amount of rent or profit which they would derive; and he was even of opinion that in this way they had retarded the progress which they sought to hasten, by leading commercial men and capitalists to believe that 5 per cent. was the maximum which could be obtained. For some time past he had been engaged in endeavouring to get gentlemen to invest money in buildings of this description, but he was met on all hands by the assertion that they did not pay. He said they did pay quite as well as they could be expected to do; and that being the case, similar undertakings, managed in a purely commercial spirit, would pay very well. Mr. Alderman Waterlow made his buildings pay, in some cases, 10, in others 9, 8, or 7 per cent., the average being an 8 per cent. rental, yielding 5 per cent. on the gross capital, a large portion of which was always unproductive. He believed the best thing which the philanthropic societies could do was to begin afresh, and endeavour to make the most they could out of their buildings, and thus remove the false impression which they had created. Then they might also get assistance from those who did not want 8 or 9 per cent.; he meant the class who were to be benefited. They were ready to combine in building societies, and in other ways to assist themselves and one another, and would render valuable help in this direction. There was a co-operative society in Edinburgh, established in 1861, the secretary of which had just informed him that they had already a paid-up capital of £10,000, and by a system of building houses, selling them, and re-employing the capital set at liberty, they had actually been able to build 212 houses and five shops in the outskirts of the town at a cost of £40,650. He thought the plan of selling the houses when completed, and re-employing the capital, was an advantageous one, and should not be lost sight of.

Professor KERR said, as a writer on this subject, he should be sorry to allow the discussion to close without attempting to introduce what he considered the practical view of the case. He felt most decidedly that the Bill of Mr. McCullagh Torrens would, if passed, give a fresh start altogether to the action which had been taken with respect to the improvement of the dwellings of the working classes, but it seemed to him that the provisions of the bill were somewhat complicated. He would, as an architect and district surveyor, suggest that there was an analogous proceeding under the Building Act with regard to dangerous structures, which, if it were inquired into, would afford to Mr.

Torrens a much easier mode of attaining his object than the one he at present proposed. When a building in London was dangerous it was considered to be existing illegally, and the law could step in and pull it down, no matter who owned it, or what impediments were thrown in the way. Therefore, if a building were injurious to health and dangerous in that way, why could not the law be made to step in and pull it down in precisely the same manner? The mode in which a dangerous structure was pulled down was simply this:—The police, on being requested to examine a building, if it were dangerous, would pronounce it so. The matter then had simply to be carried before a magistrate (in this particular case no jury being required), and if the magistrate supported the police, down the place must come. Why could not similar machinery be put in force with regard to buildings dangerous to health? Then it was a very large question how to provide better dwellings for the working classes when the old ones were pulled down, and it was one which had not been touched that evening. Three nights had been spent in its discussion at the Institute of Architects a short time previously, in consequence of a paper which he had been permitted to read, but even those three nights of discussion did not produce very much. The subject was one which it was no use touching merely on the surface, but he might just say he did not think concrete settled the question of poor men's dwellings at all. As to building a wall in concrete two-thirds the thickness of a brick wall it was perfectly out of the question. By the building act a wall 30 feet long and 25 feet high might be built 9 inches thick, and did anyone mean to say he could build that only 6 inches thick of concrete?

Mr. NEWTON said he would do so.

Professor KERR said he thought such a plan was totally impracticable.

The CHAIRMAN said he thought they had met much more to consider the political and financial mode of raising the means for erecting proper dwellings than the question of how the houses were to be constructed. He quite agreed with his friend Mr. Hawes that this matter must be considered on purely commercial principles, for it was much too large an undertaking to be carried out by mere philanthropy. He believed ten millions sterling would be required to put London into a decent and healthy condition, and it was, of course, impossible to raise such a sum as that by mere benevolence. It must be done on the commercial principle, and until they could show that there was a prospect of 8, 9, or even 10 per cent., capitalists would not even entertain the question. He must take the credit to himself of having always seen the matter in that light. The great difficulty did not lie in providing dwellings for the better class of artisans, who earned from 25s. to 30s. or 40s. a-week; they were now being provided for in a variety of ways. Houses were springing up in all directions in the suburbs, and the institution of cheap trains enabled them to travel backwards and forwards easily. No doubt there were certain classes of skilled artisans who required to live in the neighbourhood of their work, and some provision must be made for them, but that was not the great class to which they were looking, which was rather the vast mass of the population, the hand-to-mouth labourer, people who lived on a casual 13s. or 14s. a-week, perhaps not even averaging 12s. a-week all the year round. He must take a little exception to what Mr. Hawes had said about exaggeration in these matters, for he was certain no one who had dived into those haunts of misery would say there could be any exaggeration as to their shocking condition.

Mr. HAWES begged leave to explain that he only complained of exaggeration in the estimated effects of better lodgings on the rate of mortality; he did not think it was fair to put it as a reduction from 33 to 17 per cent.

The CHAIRMAN said there was no doubt that when they came to precise figures they might easily be led

into error. It might be a slight exaggeration to say that the mortality would be reduced from 34 to 17 per cent., but there could be no doubt that it would be reduced very materially. It was not only the physical but the moral effects which they had to take into account and there was no doubt that these had an immense influence on the rate of mortality. His friend Mr. Cruikshank would be rejoiced to hear that the moral improved the condition of the people—giving them plenty of fresh air and healthy rooms—their habits, they reduced the tendency to habits of intemperance. He did not think that, as had been stated by Mr. Sewell, they gave the working classes too much; if they gave them extra accommodation they made them pay for it, apartments of three rooms being let for 7s. or 8s. a-week. He believed that what was really wanted was a room for 1s. 6d. or 2s. 3d. a week, to meet the requirements of the hand-to-mouth labourer, who had no fixed wages. It was the difficulty he found in connection with Mr. McCullagh Torrens's Bill, that it made little provision except for the higher class of artisans. He protested that these wretched buildings should be pulled down, and what was to be put up in their stead? He did not contemplate the erection of a large number of houses consisting of single rooms, in which whole families were to be maintained—and though it would be objectionable, no doubt, to give such a social arrangement legal sanction, yet it was an evil which at present they must put up with, and it was by providing such limited accommodation, of the best possible kind under the circumstances, and at the lowest rate, that the most could be done. In connection with this he wished to draw attention to the operation of the Sanitary Act, which was passed in very great haste at the close of the last session, in the time of the cholera epidemic. A society with which he was connected had recently received an order from the Board of Works of the St. Giles's District, giving them twelve months in which to carry into effect all the provisions of this Act. One of the clauses required the houses to be whitewashed at least four times a year, or oftener if necessary; that all basements should be paved; that 15 gallons of water daily should be supplied to each individual; and that 400 cubic feet of air should be allowed to each person living in them. Now, this was not as if there had been a bad state of things existing in those houses. On the contrary, for a considerable number of years they had been remarkable for health and decency. They had, therefore, as good a claim to be let alone as any other. Their object had been to provide accommodation for the very poorest, and they had succeeded in bringing down the rent to 2s. a week for a single room; but, if all those regulations were to be enforced, they would have to raise the rent fully 30 per cent., and to turn out a considerable number of their tenants. He could not conceive anything more oppressive than these regulations, and their ultimate tendency would be to stop all improvements of this character. It was a serious inconvenience to a family which had but one room, to have it completely whitewashed once a year, and if that were increased to four times a year, it would be an intolerable nuisance. He believed that the Board of Works were acting in accordance with the letter, but in contradiction to the spirit, of the statute, and he hoped that they would go so far that public feeling would be aroused, and an alteration made in the law. He concluded by proposing a cordial vote of thanks to Dr. Hawksley for his most interesting paper.

Dr. HAWKSELEY, in reply, remarked that the discussion having continued to so late an hour, he did not wish to keep the meeting a moment longer than necessary, and especially as the chairman had already so completely answered many of the objections that had been advanced. He only wished to explain to Mr. Hawes that no new designs for erecting buildings for the poor had been advocated in his paper, because he considered the difficulties of the case did not

e in that direction; he thought they were much more in the nature of the means whereby to carry out the excellent and improved designs that already existed; consequently all the force of his argument had been thrown into the question of the best mode of obtaining the large amount of money necessary for the purpose. With regard to the objection of comparing the diminished mortality in the improved dwellings, not with the ordinary rate of the metropolis, but with that of the neighbourhood in which those improved dwellings were situated, he thought he had carefully protected himself from all charge of exaggeration by considering that, if seventeen per thousand be the mortality of the population in the improved dwellings, and twenty-four that of the metropolis, it followed (the mortality of the upper and middle classes in London not being more considerable than that of the inhabitants of the model lodgings) that, supposing of the three millions of population in the metropolis, two of them, represented by the upper, middle, and well-lodged of the humbler classes, corresponded to the rate of 17 per thousand, there would of necessity be a death-rate as high as 38 per thousand for the remaining million to make up the average of 24. In making the comparison therefore of 17 to 33 as the probable difference between the inhabitants of the improved dwellings and those of the squalid abodes round them, he thought he was quite within the limits of fact. He was sorry that the time would not allow him to answer the other gentlemen who had kindly assisted in the discussion, and he begged to thank Mr. Newton for his interesting information regarding concrete which accorded with that he had received through other channels.

Mr. W. E. NEWTON writes as follows:—As some of the gentlemen who spoke after me appeared somewhat sceptical as to the strength of concrete and its applicability for the construction of buildings, and seemed to think that the advocacy of this material was an "amiable weakness," it may perhaps be interesting to state the nature and composition of the concrete which has been successfully used in constructing the Emperor's "Maisons Ouvrières" in the Avenue Dumesnil, Paris, and also that used by me in the works I have carried out here. In Paris we used one part of Portland cement (C. Francis and Sons) to five parts of large gravel stones, varying in size, from the size of pearl barley to that of peas. The fine sand is sifted or screened out, put on one side, and used for making stucco for facing the work. At this place I find it more economical to use burnt brick earth, or "brick ballast," as it is called, from which I sift out the very fine, and add one of Portland cement to 8 of ballast. This makes a very hard wall. I have even reduced the cement to one in ten with perfect success. I burn the ballast myself and it costs me under 2s. per cubic yard. Therefore, if we take one yard of ballast at 2s., and 2½ bushels of cement at 1s. 10d., we shall have a cubic yard of concrete for 6s. 7d., to which add 2s. 3d. per yard for labour, and we shall find we can put up a superficial yard of nine-inch work for less than 3s. One gentleman ventured to question the possibility of building a wall 30 feet high in 9-inch work. I only say that this has been done by Mr. Tall, and the houses so constructed have been sold by him at a very large profit. From the numerous experiments I and others have made in concrete constructions, I have no hesitation in offering the following challenge to the sceptics, viz., that they shall build a wall of any dimensions in common brick and mortar with or without Tycman's bond, and I will build one in concrete; and if the concrete wall does not sustain a greater weight than the brick wall I will forfeit to them £50 and the cost of the wall, they undertaking the same liability to me should the brick wall not stand an equal test."

Mr. SAMUEL SHARP has forwarded the following statement relative to the cost of constructing dwellings of concrete for the labouring classes, viz.:—

(1.) One room, 12 ft. by 12 ft. and 7 ft. high ..	£30
(2.) Two do., ..	60
(3.) Suite of 3 rooms, scullery, and w. c. ..	100
(4.) Do. 2 do., ..	75

The saving by building of concrete and Nicol's patent partitions and roofs is 25 per cent.

Ground rent for 3 rooms, £3 per annum.

Do. 1 room 4d. to 6d. per week.

Do. 2 rooms 7d. to 10d. do.

in the centre of London; in the suburbs at least one-half less.

The foregoing calculation is without including the purchase of the land. If this is added, the sums (1), (2), (3), and (4), will be raised to £50, £100, £160, and £115 respectively.

Proceedings of Institutions.

UNION OF LANGLSHIRE AND CHESHIRE INSTITUTES.—SPECIAL PRIZES FOR 1867.—The Council of the Union offer the following extra prizes to candidates connected with Institutes in the Union:—1. Two prizes, of £1 10s. and £1, to the two candidates who shall obtain the highest aggregate number of marks at the Society of Arts' Examinations. 2. A copy of Black's Atlas will be given to the candidate who shall obtain the highest aggregate number of marks in Geography at the examinations of the Society of Arts and the Science and Art Department; donor, Mr. J. Heywood, Manchester. 3. A chemical laboratory, suitable for the private study of chemistry, will be given to the candidate who shall obtain the highest aggregate number of marks in Chemistry at the examinations of the Society of Arts and Science and Art Department; donor, Mr. Woolley, Manchester.

PARIS UNIVERSAL EXHIBITION.

The commissioners appointed by Her Majesty to advise on the best mode by which the products of industry and the fine arts of the United Kingdom, the British colonies, and dependencies, may be procured and sent to the Universal Exhibition of Works of Industry and Agriculture to be held in Paris in the year 1867, and to appoint jurors, have appointed the following as presidents, vice-presidents, jurors, and associates, to represent the United Kingdom in the International Jury.

LIST OF JURORS AND ASSOCIATE JURORS.

(The names in parentheses are associate jurors.)

Works of Art.—Paintings in oil, Viscount Hardinge (John Lealie, Esq.). Other paintings and drawings, Hon. Spencer Cowper (S. Vincent, Esq.). Sculpture and die-sinking, A. H. Layard, Esq., M.P. (W. Calder Marshall, Esq., R.A.). Architectural designs and models, J. Ferguson, Esq. (Lieut.-Colonel Scott, R.E.). Engraving and lithography, R. J. Lane, Esq., A.E.R.A., and F. Seymour Haden, Esq., F.R.C.S. (Julian Marshall, Esq.)

Apparatus and Application of the Liberal Arts.—Lord Houghton, Vice-President. Baillie Cochrane, Esq., M.P., Associate Vice-President. Printing and books, George Clowes, Esq. (C. Rivers Wilson, Esq.). Paper, stationery, binding, painting, and drawing materials, Warren de la Rue, Esq., F.R.S. (F. Hankey, Esq.). Applications of drawing and modelling to the common arts, R. Redgrave, Esq., R.A. (H. A. Bowler, Esq.). Photographic proofs and apparatus, Dr. Hugh W. Diamond (Lieutenant-Colonel Gordon, C.B. R.E.). Musical instruments, Lord Gerald Fitzgerald. (Hon. Seymour Egerton, 1st Life Guards.). Medical and surgical instruments and apparatus, Sir J. F. Olliffe, M.D. Mathematical instruments and apparatus for teaching science, C. Brooke, Esq., M.A., F.R.S. (Lieutenant-Colonel Strange, F.R.S., F.R.A.S.). Maps and geographical and cosmographical apparatus, Captain G. H.

Richards, R.N. (Lieutenant-Colonel A. C. Cooke, R.E., F.R.G.S.).

Furniture and other Objects for the Use of Dwellings.—Fancy furniture, J. H. Pollen, Esq., M.A. Upholstery and decorative work, Matthew Digby Wyatt, Esq., F.S.A. Crystal fancy glass and stained glass, E. W. Cooke, Esq., R.A., F.R.S. (Henry Chance, Esq.). Porcelain, earthenware, and other fancy pottery, Right Hon. W. E. Gladstone, D.C.L., M.P. (J. C. Robinson, Esq., F.S.A.). Carpets, tapestry, and other stuffs for furniture, Peter Graham, Esq. Paper hangings, J. G. Crace, Esq. Cutlery, G. Wolstenholme, Esq. (C. Asprey, Esq.). Gold and silver plate, Percy W. Doyle, Esq., C.B. (G. J. Cayley, Esq.). Bronzes and other art castings and repoussé work, no juror allowed. Clocks and watches, C. Frodsham, Esq. Apparatus and processes for heating and lighting, Professor J. Tyndall, LL.D., F.R.S. (Rear-Admiral Ryder, R.N., C.B.). Perfumery, Dr. W. Odling, F.R.S. Leather work, fancy articles, and basket work, J. M. Stanley, Esq. (F. West, Esq.).

Clothing (including Fabrics) and other Objects worn on the Person.—Duke of Manchester, President; the Right Hon. Sir W. Hutt, M.P., K.C.B., Associate President. —Cotton thread and fabrics, Malcolm Ross, Esq. Thread and fabrics of flax, William Spotten, Esq. Combed wool and worsted fabrics, W. Morris, Esq. (J. Law, Esq.). Carled wool and woollen fabrics, Edward Huth, Esq. (H. S. Way, Esq.). Silk and silk manufactures, Sir B. S. Phillips (C. S. Haden, Esq.). Shawls, W. H. Clabburn, Esq. Lace, net, embroidery, and small ware manufactures, Daniel Biddle, Esq. (Thomas Ball, Esq.). Hosiery and under-clothing, and articles appertaining thereto, A. J. Mundella, Esq. Clothing for both sexes, Lieut.-Colonel Hudson. Jewellery and precious stones, Earl Dudley (N. H. M. S. Maskelyne, Esq.). Portable weapons, arms, and military equipment, Major-General Sir W. Gordon, R.E., K.C.B. (Major-General C. Dickson, R.A., C.B.). Travelling articles and camp equipage, Sir S. Baker and Edward Page, Esq. (M'Leod of M'Leod). Toys, no juror allowed.

Products (Raw and Manufactured) of Mining Industry, Forestry, &c.—Mining and Metallurgy, S. H. Blackwell, Esq. (Captain W. S. Roden). Products of the cultivation of forests, and of the trades appertaining thereto, Hon. F. D. M'Gee (P. L. Simmonds, Esq.). Products of shooting, fishing, and of the gathering of fruits obtained without cultivation, Professor Wyville Thomson, F.R.S. Agricultural products (not used as food) easily preserved, D. Hanbury, Esq. (Dr. T. Thomson, F.R.S.). Chemical and pharmaceutical products, Dr. Frankland, F.R.S. (Dr. David Price). Specimens of the chemical processes for bleaching, dyeing, printing, and dressing, Sir Robert Kane, F.R.S. (Dr. David Price). Leather and skins, Dr. Forbes Watson, A.M., F.R.S. (J. Evershed, Esq.).

Apparatus and Processes Used in the Common Arts.—Lord Richard Grosvenor, M.P., Vice-President; H. C. E. Childers, Esq., M.P., Associate Vice-President. Apparatus and processes of the art of mining and metallurgy, W. Warrington Smyth, Esq., M.A., F.R.S., Pres., G.S. (Dr. C. Le Neve Foster, F.G.S.). Agricultural apparatus and processes used in the cultivation of fields and forests, Jacob Wilson, Esq. Apparatus used in shooting, fishing-tackle, and implements used in gathering fruits obtained without culture, Col. Hon. F. H. Keane (Major Edwards, R.E.). Apparatus and processes used in agricultural works and in works for the preparation of food, James C. Amos, Esq. (C. Wren Hoskyns, Esq.). Apparatus used in chemistry, pharmacy, and in tan-yards, Dr. Lyon Playfair, C.B., F.R.S. (Professor T. C. Archer). Prime-movers, boilers, and engines especially adapted to the requirements of the exhibition, J. Scott Russell, Esq., M.A., F.R.S. (Captain Beaumont, R.E.). Machines and apparatus in general, the Earl of Caithness and Robert Mallet, Esqrs., Mem.I.C.E., F.R.S. (John Anderson, Esq.). Machine tools, G. W. Hemans, Esq., Mem.I.C.E., F.R.G.S., F.G.S. Apparatus and processes used in

spinning and rope-making, R. D. Marshall, Esq. Apparatus and processes used in weaving, M. Curtis, Esq. Apparatus and processes for sewing and for making clothing, Peter Tait, Esq. (Captain Ponsonby, R.E.). Apparatus and processes used in the manufacture of furniture and objects for dwellings, Lieut. Colonel Ewart, R.E. Apparatus and processes used in paper-making, dyeing and printing, Wyndham Portal, Esq. Machines, instruments, and processes used in various works, C. F. Bayer, Esq. Carriages and wheelwrights' work, G. N. Hooper, Esq. Harness and saddlery, Captain Fenn (Henry Göschen, Esq.). Railway apparatus, J. E. McConnell, Esq., Mem.I.C.E. (D. Campbell, Bart.). Telegraph apparatus and processes, C. Wheatstone, Esq., F.R.S. (Lord Selkirk Cecil). Civil engineering, public works, and architecture, C. H. Gregory, Esq., Mem.I.C.E. (Major A. G. R.E.). Navigation and life-boats, Captain E. A. (Rev. J. Woolley, LL.D.).

Food (Fresh or Preserved) in Various States of Preparation.—Cereals and other eatable farinaceous products and the products derived from them, J. Druce, Esq. (J. Woolton, Esq.). Bread and pastry, no juror allowed. Fatty substances used as food, milk and eggs, no juror allowed. Meat and fish, no juror allowed. Vegetables and fruit, no juror allowed. Condiments and stimulants, sugar and confectionary, G. M. Esq., M.P. Fermented drinks, Hon. H. G. Hay (E. L. Beckwith, Esq.).

Live Stock and Specimens of Agricultural Buildings.—Farm buildings and agricultural works, no juror allowed. Asses, horses, mules, M. Higgins, Esq. (Captain C. C. Bull, Esq.). Bulls, Buffaloes, &c. Sheep, goats, rabbits. Poultry. Sporting dogs and watch dogs. Useful insects. Fish, crustacea, and mollusca. No jurors allowed.

Live Produce and Specimens of Horticultural Works.—Duke of Cleveland, K.G., president. Hothouses and horticultural apparatus, Professor Balfour, M.D. (Dr. Thomson, F.R.S., also in raw and manufactured products). Flowers and ornamental plants. Vegetables. Fruit trees, no jurors allowed. Seeds and saplings of forest trees, Dr. J. D. Hooker, F.R.S. (Dr. Macdonald). Hot-house plants, James Veitch, Esq. (F. W. Esq., Esq., Q.C.).

Articles Exhibited with the Special Object of Improving the Physical and Moral Condition of the People.—Sir J. P. Kay-Shuttleworth, Bart., vice-president. Apparatus and methods used in the instruction of children, Rev. Canon Norris, M.A. (E. C. Johnson, Esq.). Libraries and apparatus used in the instruction of adults at home, in the workshop, or in schools and colleges, Rev. W. Rogers, M.A. (Rev. M. Mitchell, M.A.). Furniture, clothing, and food from all sources, remarkable for useful qualities combined with cheapness, Viscount Canterbury (Nassau J. Senior, Esq.). Specimens of the clothing worn by the people of different countries, no juror allowed. Examples of dwellings characterised by cheapness combined with the conditions necessary for health and comfort, no juror allowed. Articles of all kinds manufactured by skilled workmen, no juror allowed. Instruments and modes of work peculiar to skilled workmen, no juror allowed.

(Signed) ALBERT EDWARD, P.

OPENING OF THE PARIS EXHIBITION.

The exhibition was duly opened on Monday, April 1st, according to the original arrangement. His Majesty the Emperor, accompanied by the Empress, arrived at the chief entrance to the park and passed up the main avenue to the chief door of the building.

Within a few days the appearance of this part of the park has undergone an extraordinary change; tall Venetian masts, painted green and relieved by gilding, have been set up on each side along the entire length of the avenue, about five hundred feet, and between these, at

1-height, are stretched a series of strong squares of canvas, covered on the under side with a handsome green material, powdered with golden bees. These squares are fitted to each other by means of a series of hooks, and form a truly imperial canopy along the entire route, the effect being greatly heightened by a bordering of the same material as the velum, dentated and enriched with bold pattern in gold embroidery. At the top of the canopy, and also on the flag staves on the building itself, at brilliant pennons, which give a festive air to the whole scene and relieve the effect of the massive iron structure in a very agreeable manner.

Entering the building by the chief door, the imperial party halted for a few moments in the open space in the great machinery court, between the limits of the French and English sections. The two sides of this space present a curious contrast; on the French are trophies of iron and brass work and materials, towering up to within a few feet of the spring of the roof, while on the English side stands the Victoria gold pyramid, which since 1862 has grown to the height of sixty or seventy feet; around its base are ranged the steam cranes which have performed signal service in the arrangement of the British section, and on the opposite side of the gallery and an English pillar post-box, a series of sorting tables, and other post-office materials, and a beautiful model railway with a travelling post-office, consisting of three vans, that in the centre acting as a tender to the other two, and being fitted with the ingenious apparatus for taking in and delivering the mails *en route*. These models are made to the scale of 1 in 4, are beautifully made, and exhibit the whole arrangement in an admirable manner. On one of the descriptive blinds of the great windows above, the invention, if the expression may be used in such a case, of penny postage is recorded in full characters beneath Sir Rowland Hill's name.

Starting from this point, the imperial party and suite made the complete tour of the machinery court by the spectators' gallery in the centre.

The sides of this gallery are carried out at intervals so as to form niches, and in these latter the foreign commissioners and jurors, each party in their own "sector" of the building, were placed and presented to their Majesties in succession.

The whole of the machinery and other articles exhibited in this great court are not yet in perfect order, but there are very few vacant spaces, and the mass collected within the iron walls is prodigious.

Having made the complete circuit of the building, their Majesties passed through the grand vestibule to the French Fine Art Court. The vestibule does not possess the magnificent proportions of the grand naves of either of the previous Universal Exhibitions, and its roof is heavy, both in form and colour. Nearly the whole of the clerestory windows, both on the French and English sides, are filled with stained glass, much of it brilliant in colour, and generally, though not universally, harmonious; while the bays below exhibited a splendid collection of wares of various kinds. On the English side these bays, which form the termini of the various groups, have been completely arranged for some days, and called forth great admiration. The beautiful casts of the sculptured works from Campo Santo and St. Jago have already been mentioned. Near these stands a magnificent chimney-piece, in alabaster, with inlaid panels and cameos, by Wedgwood; a splendid collection of china vases, majolica, and other wares, by Minton and Copeland; a number of Elkington's beautiful reproductions; some good furniture, and other articles. On the French side, the arrangements were not sufficiently advanced to allow of anything like a complete show.

From the vestibule their Majesties entered the French portion of the Fine Art Gallery, and again made the tour of the building, though by a much more contracted zone; two *défilés* were also made across the central zones, occupied by the industrial groups, by the two principal

side avenues of the building, the Rue de France and the Rue de Russie.

In the various sections of the Fine Art galleries were stationed the ministers and officers of state, the diplomatic body, those ladies and gentlemen who had been honoured with special invitations, together with the foreign commissioners, jurors, and others who had quitted the gallery in the Machinery Court after the passage of the Imperial party.

The last section visited was the English Fine Art Court, and quitting this their Majesties passed across the enclosed garden along the avenue at the opposite side of the building, the Rue de Belgique and the park, by the gate opposite to that by which they had entered.

A good deal still remains to be done in the way of final arrangement, but the Exhibition presented on the whole a very creditable appearance, considering the vastness of its plan and the space which it occupies. The Russian, Swedish, Danish, and English departments may be said to be complete; in nearly all other sections of the building the imperfections were more numerous.

The picture galleries have all their walls nearly covered; the English gallery was not only arranged but matted and comfortable, and the whole collection of pictures is, beyond question, one of the finest that has been seen since 1855.

The weather was magnificent for April, indeed, it would have been fine for May; the sun was never once crossed by a cloud. The number of persons present was large—it is impossible to say how large—and the opening of the Exhibition, although not a ceremonial, must be considered a success.

Publications Issued.

PARIS UNIVERSAL EXHIBITION, 1867: THE COMPLETE OFFICIAL CATALOGUE, ENGLISH VERSION. Published under the authority of the Imperial Commission, by J. M. Johnson and Sons, Castle-street, Holborn, London; F. Dentu, Paris, Editeur de la Commission Impériale. This version was translated from the proof sheets of the French Catalogue, published by the Imperial Commission, and it is believed that this is the first instance in the history of International Exhibitions in which a complete catalogue has been prepared in a language foreign to the people where the exhibition was held. The translation was made by Mr. G. W. Yapp, who, as stated in the preface, only received the principal part of his copy within the last month, so that the volume has been produced with extraordinary rapidity, as it was in the hands of the public on the 29th ult. The price is 5s.

PARIS UNIVERSAL EXHIBITION, 1867.—CATALOGUE OF THE BRITISH SECTION. Printed for Her Britannic Majesty's Commissioners, and sold by Spottiswoode and Co.—This work contains a list of the exhibitors of the United Kingdom and its colonies, and the objects which they exhibit, and is in four different languages, English, French, German, and Italian. The introduction includes a brief account of the three previous International Exhibitions, and a statistical summary of the industries and commerce of the United Kingdom, prepared in accordance with the wishes of the French Commission. There is an illustrated appendix, containing detailed notices of many of the objects exhibited, the whole forming a thick volume, price 3s. 6d.

Correspondence.

MR. YOUNG'S PAPER ON FLAX.—SIR,—In your report of the discussion on Mr. Young's paper on "Flax," read

on Wednesday, the 27th ult., there is an inaccuracy in the first part of my remarks, which I shall be much obliged by your correcting. Instead of "800 acres of land, and producing about 3,000 tons of flax per annum," please read, "800 acres of land, or about 3,000 tons of *flax straw* per annum." Also my name is as undersigned. I am, &c.,
JOHN C. WILSON.

East India House, 5, Lime-street, March 30, 1867.

MEETINGS FOR THE ENSUING WEEK.

- Mon.....** Society of Arts, 8. Cantor Lecture. Mr. John Hullah, "On Music and Musical Instruments."
London Inst., 7. Prof. Westwood, "On Entomology."
R. United Service Inst., 8½. Capt. Majendie, "On Military Breech-loading Small Arms."
R. Geographical, 8½. 1. Lieut. J. B. Bewaher, "Site of Kanana and Ancient Canals in Mesopotamia." 2. Mr. J. E. Taylor, "Sources of the Lycos and other Rivers in Kurdistan." 3. Mr. R. J. Garden, "Description of Diarbekr."

Patents.

From Commissioners of Patents' Journal, March 29th.

GRANTS OF PROVISIONAL PROTECTION.

Ball or supply valves—690—J. Pearson.
Boots, &c.—418—T. Greenwood and J. Keats.
Boots, &c., cleaning—655—H. Churchman and F. Braby.
Bottles, &c., stopping—689—P. Duchamp.
Breech-loading fire-arms and cartridges—717—M. A. F. Mennons.
Bridles and reins—675—J. G. Tongue.
Bulding springs—704—H. L. Corlett.
Candles, ornamenting—671—A. Field and W. B. Nation.
Charcoal, animal—707—J. F. Brinjes.
Clay, utilizing—664—A. McDougall.
Electric telegraph conductors—694—D. Nicoll.
Engines—633—A. L. Normandy.
Fabrics, drying—695—W. Clark.
Fabrics, mangling—653—C. Mather.
Fibres, &c., twisting, &c.—641—W. Dyson.
Fibrous materials, cleansing—713—J. L. Norton.
Fibrous materials, preparing—655—S. Shore.
Fibrous materials, spinning, &c.—627—H. Barton and E. Whalley.
Fibrous materials, spinning, &c.—693—W. Dempsey.
Fibrous substances, grinding—714—W. Wood.
Filtering presses—657—E. T. Hughes.
Fire-arms, breech-loading—592—W. P. Gray.
Fire-arms, breech-loading—537—J. R. Cooper.
Fire-arms, breech-loading—677—M. A. F. Mennons.
Fire ranges—635—E. K. Heaps and T. P. Moorwood.
Fluids, measuring—631—C. W. Siemens.
Gas, &c., combusting—692—E. T. Hughes.
Hooks, hat and coat—710—J. A. Fussell.
Hops, drying—620—W. H. Samson.
Horse's feet, coverings for—633—G. Haseltine.
Horse-shoes—695—W. Akers.
Iron, &c., coating—657—J. Turner.

Knobs—691—J. B. Kenby.
Ladies' garments, springs for—645—L. H. Philbott and A. M. Lampe—667—G. Dümmler.
Land, tilling—497—J. Phillips-Smith.
Light, &c., obtaining—458—J. H. Johnson.
Lockets—646—T. B. Turnbull.
Metallic bedsteads—639—R. Luke and W. Parkes.
Minerals, mining, &c.—635—A. Howat.
Mines, ventilating—552—C. J. Pownall.
Mixing apparatus—637—A. Giles.
Motive power engines—700—R. Wilson.
Mud, &c., mowing—702—T. Burt.
Paper—647—E. Lloyd.
Piston-rods, &c., packing for—648—J. McIlintock.
Propulsion—696—M. P. W. Boulton.
Pterotypes—3183—J. Pratt.
Railways—549—A. V. Newton.
Railway signals, &c.—647—J. Livesey, J. Edwards, and W. J. Safety valves—643—A. V. Newton.
Sash fastenings—663—M. Cavanagh.
Sewing machines—697—A. Kimball.
Sizing and dressing machines—673—W. B. Lowe.
Slop pall and night commode, &c. combined—706—A. Paton.
D. Sweeney.
Steam boilers—661—C. Mace.
Steam boilers—679—R. D. Napier.
Steam, generating—614—J. C. B. Weguelin and B. Hin.
Steam, generating—645—J. G. Woodward.
Taps and valves—609—C. Maschwitz, jun.
Textile fabrics, printing on—346—E. E. Green and W. Lloyd.
Valves—703—B. P. Walker.
Vulcanite, baking—689—F. Ryding.
Washing machines—697—M. Chamberlaine.
Weaving, looms for—716—W. J. Sleath and J. Hargreaves.
Weaving, looms for—719—J. Boyd.
Wheel moulding machines—715—J. Willcock and S. Mearns.
Yarns, winding, &c.—712—W. Hall.

FRIDAY, APRIL 12, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

APRIL 17.—*Passion Week.* No MEETING.

CANTOR LECTURES.

MR. HULLAH's course, "On Music and Musical Instruments," will be extended by two additional lectures, as follows:—

LECTURE VII.—MONDAY, APRIL 29.

MUSICAL INSTRUMENTS (*continued*).—The Bow—The Key-board—The Violin—The Organ—The Clavichord.

LECTURE VIII.—MONDAY, MAY 6.

MODERN INSTRUMENTS, CHAMBER AND ORCHESTRAL.—The Pianoforte—Combination of Instruments—The Orchestra.

The lectures commence at eight o'clock, and are open to members, each of whom has the privilege of introducing one friend.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Countts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

The Sub-Committee on Milk met on Wednesday, March 20th. Present—Mr. Benjamin Shaw, in the Chair; Mr. James Caird, Mr. Harry Chester, Mr. McClagan, M.P., Mr. C. S. Read, M.P., Mr. Ludford White, and Mr. E. Wilson.

MR. ALEXANDER WOOD (having attended on the invitation of the sub-committee) stated that he was Deputy-Chairman of the Great Western Railway, and was acquainted with the general arrangements for the transit of milk on that line. Milk had been carried on that line for some years, but the extension of that traffic was best shown by the return he had before him, which gave the quantity of milk carried monthly from January, 1865, to February, 1867, and during that interval the increase in the quantity carried was very large. In the month of January, 1865, there were carried 1,051 cans, containing 8,954 gallons, and realising a revenue of

£55 1s. 10d. In January, 1866, the quantity carried during that month was 12,611 cans; so that in one year it jumped up from 1,051 cans to 12,611, containing 143,600 gallons, which was a very large increase in so short a time, and the revenue had increased from £55 odd to £719. That was about the period when the rinderpest was at its height, and no doubt that marked increase in the quantity of milk sent to London from the country dairy districts was due to the disappearance of the cows from the London cow-sheds. Going on to January in the present year he found the quantity was rather stationary. In that month the number of cans carried was 12,639, containing 143,588 gallons, producing a revenue of £718 16s. 5d. That was very nearly, indeed, the quantity that was carried in the corresponding month of 1866. During the last twelvemonths the trade had been almost stationary, not having much increased. In the intermediate months there was sometimes an increase, but it went down again afterwards. At the present time the quantity carried was slightly on the decrease. The largest quantity carried in any one month was in May last, when there were 16,706 cans, containing 285,918 gallons. In June there was not much difference; in that month there were 16,000 cans and 221,851 gallons. The larger quantity of this milk came from Purton, about six miles below Swindon, and 100 miles from London. At Swindon you get into the dairy districts of Wiltshire. The supply begins in the long valley of Berkshire, below Reading, and there you get into the grass country continuing to below Swindon.

MR. CHESTER—Do the directors of the Great-Western Railway take any special steps to encourage this traffic, or is the supply left to develop itself?

MR. WOOD—This traffic has sprung up very suddenly, and the traffic-managers have been compelled to do the best they could to meet the sudden wants of the trade, and of course they take pains to do so. A number of old second-class carriages were as quickly as possible converted into milk-vans; but with regard to the cans in which the milk was carried the trade provided them.

MR. CHESTER—Are there any regulations as to the size and shape of the milk-cans?

MR. WOOD—No; it was difficult to insist upon the traders, who found their own vessels, conforming to a particular description of can. When this milk-trade commenced, knowing that there is a very large milk-trade on the French railways, the general manager put himself in communication with officials in Paris, and obtained a specimen of the cans used in France. He was sorry they had not been able to induce the trade here to use a uniform description of can.

MR. CAIRD—Do you consider that the French cans are better adapted for the purpose than those used in this country?

MR. WOOD thought they were. The French cans were only about half the size of those used here. Our cans were much too large and too heavy to be loaded and handled by one man. Whether the larger bulk of milk carried in each can had a prejudicial effect upon the milk he was unable to say; but with regard to the handling of the cans at the stations, he thought the smaller-sized cans used in France were more convenient. The shape of the French cans was more convenient for packing in the vans. Our cans are broad at the bottom and tapering towards the top. The French cans, from their shape, could be packed with greater economy of space. The French milk trucks are very much like the narrow-gauge sheep-truck used in this country, with two floors, one above the other—two tiers, in which a great number of cans could be packed, and there was a circulation of air all round them. He thought one of the defects in carrying milk was carrying the cans in enclosed vans, because there was sometimes an escape of milk, which became sour, and he thought a circulation of air through the van was beneficial.

MR. CHESTER—Are you aware whether the milk cans in France have any covering over them in hot weather?

Mr. WOOD—Yes; they have a linen covering, which is watered and kept wet. We had recommended our officers to invite traders to do the same thing in summer-time; but only a few put a hayband round the top of the cans. In France the linen cover completely envelopes the cans, and when they were brought from a long distance they are watered during the journey, and the evaporation keeps the milk cool. The great merit he saw in the French cans was this. In carrying milk long distances by railway there was difficulty in preventing its churning, and the milk, when that process had commenced, was less valuable, from being carried a long distance, than milk which was brought from a much less distance in which no churning had taken place; and in which there was no separation of the fatty matters by the motion of travelling. The French get over that difficulty by completely filling the cans, and by having the top so arranged that it dips into the milk, and is kept in place by a screw stopper. By this means the milk becomes fixed tightly in the vessel, and thus no churning can take place.

Mr. READ—Have you any specimens of the French milk cans here?

Mr. WOOD believed there was one at Paddington, which he would be happy to send for the inspection of the committee. He did not consider the milk cans used in this country were adapted for carrying milk long distances. The cans were closed by a perforated top, and sometimes with a cloth round it, and if these cloths were not carefully washed there was an impurity which tainted the milk. The treatment of milk required the greatest cleanliness throughout. These cloths were sent backwards and forwards, and were not always as clean as they ought to be. The perforated top was so made because the milk was too frequently put in hot. It should be quite cold before it is despatched.

The CHAIRMAN remarked that he understood one difficulty with regard to the supply of milk to London from the provinces was with regard to cream. Till the milk could be brought in a state to yield cream, the case for the abolition of the London cow sheds was not met.

Mr. WOOD said, having occasion to go to Paris on railway business he made a point of seeing how the milk traffic was carried on on the Western of France railway.

The CHAIRMAN—Does not the deterioration or not of the milk depend a good deal upon the springs of the truck in which it is carried?

Mr. WOOD replied: If the milk were properly secured in the cans in the way he had pointed out, there was, he thought, a remedy at once against churning.

Mr. CAIRD—The milk-trade in Paris is very considerable. Have the railway companies provided any special carriages for the conveyance of the milk, so as to furnish a supply of air to the cans in the transit; and has there been, as far as you are aware, anything of the same kind done on the English railways?

Mr. WOOD apprehended the traffic in milk was not at present, on any railway in this country, of sufficient extent to lead any company to provide special trains for its conveyance, further than he had pointed out in the conversion of carriages for the purpose, as had been done on the Great Western.

Mr. CAIRD—Is it a new trade?

Mr. WOOD—Comparatively a new trade.

Mr. CAIRD—Looking to the probabilities of the increase of this traffic, do you think the railway companies would be likely to provide special vehicles for the carriage of milk?

Mr. WOOD said that as he had before stated, there had been lately no marked increase in the quantity of milk carried on the Great Western Railway; at the same time he considered it would be to the interest of the railway companies to promote this traffic as much as possible, and to give every facility for it.

Mr. WHITE—Do you think the traffic in milk on the

Great Western is sufficient to warrant the company providing daily special trains for it?

Mr. WOOD said it was to the interest, both of the company and the producers of milk, to make the arrangements for its carriage as perfect as possible. He had put the question to the traffic superintendent, as to whether the milk traffic was large enough for special quick trains, and he expressed an opinion that it was not, at present. In France there were, he believed, special milk trains, but there was this difference: in France, as far as he could ascertain—they were ~~sent~~ with one train per day, in and out, consequently milking per day only was sent out. It was so on the Western of France. Two trains per day would be required for the milk trade of London.

Mr. CAIRD—Was Mr. WOOD aware whether there were any special arrangements made by the railway companies for the distribution of the milk when it reached Paris?

Mr. WOOD—There, again, there was a difference. As far as he was able to observe, in Paris a ~~union~~ description of van was employed in taking the milk from the station and bringing back the empty cans. He was not aware whether that was an organisation on the part of the railway company or on that of any individual or company formed for the purpose.

Mr. CAIRD, looking to the fact that milk was ~~reduced~~ in London to the consumers at a price more than 100 per cent. beyond what the dealers paid to the producers, suggested that the price to the consumers might be reduced, by an organised system for the distribution of the milk on its arrival in London, as compared with the present system. He would be glad to hear from Mr. WOOD whether he thought there were any means by which the railways could bring the milk more within the reach of the consumers, and, at the same time, get a larger proportion of profit to the producer.

Mr. WOOD—He did not prosecute his inquiries beyond the transit on the railway. But, as he had said, he observed, on the arrival of a milk train, carts of the new construction were employed in carrying the milk from the station, and the same description of vehicles brought back the empty cans. He could not say whether the carts belonged to the administration of the railway, or whether they were provided by intermediate parties who devoted themselves to the transit of this description of cans to and from the railway station. He had no doubt, by arrangement at the clearing house, the railway managers might be able to agree upon the right form of can, and he had no doubt the railway companies generally would adopt them. The milk was not delivered by the company in the case of the Great Western Railway when it reached Paddington; the rate of carriage was so low it would not pay the company to deliver. At present the milk was brought by slow passenger trains—not parliamentary trains, but mixed trains, which stopped at most of the stations. If the traffic could be brought into greater regularity it would assist the service, because there was great delay in moving these large cans from the stations.

Mr. CHESTER—Are the English milk cans single-skinned or not?

Mr. WOOD—Single-skinned. The linen covering over the French cans completely envelopes them; and being kept wetted, cooling is effected by the evaporation going on as they pass through the air. Possibly, the heat being greater in France than in this country makes such an arrangement for keeping the milk cool more necessary.

The CHAIRMAN—As soon as it could be proved that the milk could be brought to London in a satisfactory condition for the use of the consumers, it would no doubt assist the movement that was going on in many of the metropolitan parishes for the entire abolition of the London cow-sheds.

Mr. CAIRD remarked that it was the custom of railway companies to deliver certain goods; and he suggested

whether a sufficient rate might not be charged for the conveyance of the milk to cover the expense of delivering it to the consignees, under arrangements that would assure this being done as rapidly as possible after its arrival.

Mr. WOOD saw no reason why the milk rates should not include delivery by the company.

Mr. CAIRD suggested that would probably reduce the cost of distributing the milk in London.

Mr. WOOD hardly knew as to that, but as at present every owner of a milk walk had his own conveyance, the trade generally would have to be consulted.

Mr. CAIRD—Inasmuch as the different large milk dealers will receive their supply on their own premises, instead of having to send special conveyances of their own to take the milk from the station.

Mr. WHITE suggested that, in the delivery of an article like milk, time was a very important element. The milk was required to be distributed in London at certain times to suit the trade of the retailers.

Mr. WOOD—With regard to the speed of delivery, the people who went to the station for the milk would be likely to get it conveyed to their premises as speedily as possible. He did not think any arrangements of the kind suggested on the part of the company would expedite the distribution of the milk in London. He was disposed to think, if a very large development of the milk trade took place, some intermediate agency might spring up for the delivery to the dealers. Private enterprise generally springs up in such cases to provide what was wanted if the business was large enough to require it.

Mr. CHESTER—Is it found that in proportion as the quantity of milk carried on the Great Western increased, the quantity of butter carried on the line diminished?

Mr. WOOD replied that he had no statistics of the quantity of butter brought by the railway from these districts, but he had no doubt the quantity of butter brought over that line, as soon as the extended communication with Ireland was completed, would be immense. At the present time very little fresh butter was sent up the line, but he believed sufficient butter might be sent from Ireland for the supply of the whole of London. At present barely any fresh butter reached the metropolis from Ireland; but when he told the committee that the value of the salt butter sold in Cork market, the year before last, amounted to a million and a half sterling, when quick communication between this country and the south of Ireland was established, it might be conceived that the enhanced price of fresh over salted butter would lead to the introduction of very large supplies of that article from Ireland into the metropolis. He believed any quantity of butter that was required might be had from the south of Ireland. The shortest sea-passage was from Milford Haven, but it was the longest land route. There was this peculiarity about Milford Haven, that it was not a tidal port. A trade in fresh butter from Ireland presupposed quick transit; and butter was an article that must be conveyed rapidly, and should be subjected to as little handling in trans-shipment as possible. When the new Metropolitan Market was opened next year, the railway arrangements in connection with it would be such that the produce of fresh provisions from the south of Ireland could be brought direct into the market without any handling at all.

Mr. C. S. READ—Does much fresh butter at present come to London from South Wales?

Mr. WOOD—Very little, if any, butter was sent from that district, because the consumption was very large amongst the numerous population employed in the works of that district. They were importers rather than exporters of butter. Butter and provisions of that description were sent from Pembroke and Glamorgan to the works. The great producing country for all fresh provisions was Ireland; but private enterprise in the South hitherto, unfortunately, had not been much directed to that trade. The year before last he visited Waterford, to ascertain whether there was any large

trade in the export of fresh butter from that place; but he found that although the quantity brought into the market was large, only one person was engaged in sending fresh butter from Waterford to London; but he believed that business was extending. Two new steamers were about to be put on that line; at present the steamers were not very rapid. There were rates for the carriage of butter on the Great Western Railway. Cork was the great market for salted butter, and the landed interest and country gentlemen there were very anxious to open out the fresh butter trade with this country. There was a great peculiarity in the butter trade of Cork. Both buyers and sellers of butter in the Cork market were subjected to the rules of the market. It was thought by some persons that those rules had a prejudicial effect upon the trade of the market, and an unsuccessful attempt was made last year to alter them. Law proceedings took place; the trial lasted nearly a fortnight, and the result was to uphold the rules of the market; so that at present the butter trade of Cork was exclusively in salted butter, from which all foreigners were excluded.

Mr. WHITE—Would an English buyer, in this sense, be regarded as a foreigner?

Mr. WOOD—Every buyer, whether Irish or English, was so regarded. The reasons were these:—The Cork butter was sold for export and shipping purposes; and to keep up the brand, all butter brought into the market was subjected to a certain test, and the casks were branded accordingly. There might have been reasons for the original introduction of these rules, but there were some people who thought they were now carried too far, and that they interfered with free trade. It would be a great boon to this country to establish quick communication with the south of Ireland for the fresh provision trade. The great difficulty was to establish steam communication, on account of the expense. His own company had not yet organised a service, because it was thought that the best time to introduce this produce would be when the new Smithfield Market was opened, to which access would be had by the railway, and he believed that would be completed in twelve or sixteen months from this time. The trains would then go in underneath the market, and the produce brought would be raised by lifts direct into it so that all the intermediate handling of the provisions, which was so prejudicial to them, would be obviated, and the produce would arrive in the finest possible condition. A prejudicial effect upon fresh provisions brought to London at present was produced by the handling between the arrival at the railway station and its delivery in the market, and that especially applied to the dead meat trade.

The CHAIRMAN—Would the New Smithfield Market include such articles as butter?

Mr. WOOD—He believed arrangements would be made for trade in all articles of fresh provisions. Mr. Taylor, the Chairman of the Market Committee, would probably be able to give this Committee valuable information on these points.

Mr. CHESTER—Would any large traffic in Devonshire clotted cream be carried on on the Great Western Railway?

Mr. WOOD said he had no details with respect to that.

Mr. WHITE—Did Mr. WOOD consider milk was more injured by being conveyed 100 miles than 25 miles?

Mr. WOOD thought under proper management milk might be carried long distances without material deterioration. The limit of distance would be the cost of the carriage. He thought it would be only during a short period of the year, when the weather was hottest (if at all), that the linen coverings of the cans would be necessary, if the cans were completely filled so as to prevent the milk being shaken, and if they were carried in trucks which admitted a free current of air through them. If the London trade would be satisfied with one delivery of milk per day, the

traffic could be very easily managed; but at present two deliveries per day were required. There might, he thought, be arrangements for a milk train to run at night, and that would be a good thing during the very hot weather.

Mr. CHESTER inquired whether, in the opinion of Mr. Wood, it would be useful if the Society of Arts offered a premium for an improved milk can, and another premium for an improved milk carriage for the railways.

Mr. WOOD thought it would be extremely useful, and it would no doubt lead to a good competition in both these matters. If that were done he had no doubt the people in the carriage department of his own railway would be competitors for the improved milk van. If this committee were now on the subject of meat he would suggest that good might be done by the offer of a premium by the society for an improved meat van, to be used on railways, because there was great difficulty in the structure of a proper meat van, and he had no doubt the offer of a premium would lead to some valuable suggestions. They wanted air and even temperature; but while admitting air they had difficulty in keeping out dust. At present there was difficulty in the carriage of meat on railways. If it was suspended, and the weight was on the top of the van, that was objectionable in rapid travelling by railway, from the vehicle being top-heavy. It was well known that fresh meat was very much deteriorated by frequent handling, and in any improved van he thought attention should be given to providing a means for obviating as much as possible the necessity for handling the meat in the transit from the railway to the market. The more untouched the provisions arrived in the market the better their appearance was. On the subject of the carriage of live cattle from Ireland and the Continent, Mr. Wood stated that, from the examinations he had made into that matter, he was of opinion that there must be soon a great change in the mode of conducting the transit of live animals. He had no doubt that the injury done to the agricultural interest of Ireland by the mode of transit of live stock was beyond what people would credit except those who had gone into the subject. The rapid passing of objects on a railway in the present cattle trucks had a great effect upon the brain of the animal, and no doubt that affected the state of the blood; and the way in which they were obliged to be arranged in the trucks for the sake of economy of space, had also a very deteriorating effect upon the animals in a long journey.

Mr. WOOD inquired whether Mr. Wood had the means of knowing to what extent an animal was likely to be deteriorated in weight by the journey from Ireland to this country?

Mr. WOOD could not state what the loss of weight was, but he had been informed that dead meat sent from Aberdeen to the London market would remain good for at least two days longer than that of the animals which were brought from a long distance and slaughtered in London. He thought the powers of the Board of Trade, under the Coasting Passenger Steamers Act should be extended to the exercising of control over the cattle steamers; and that the cross-channel trade in cattle should be restricted to boats specially licensed for that purpose. There was, no doubt, a vast amount of cruelty to which the animals were exposed in the sea-passage; and he believed he quite spoke within limits when he said the cattle brought over to this country from Ireland suffered a great deterioration of their value. In conclusion, Mr. Wood stated that under arrangements which were now being carried out, he had no doubt a very large augmentation would take place shortly in the supplies of all kinds of fresh provisions from Ireland, and especially in that of fish.

The chair was then taken by the Right Hon. H. A. Bruce, M.P.

Mr. NICHOLSON, in reply to interrogations put by Mr.

Chester and other members of the Sub-Committee stated that he was chief clerk of the parcels department of the Great Western Railway Company, and was acquainted with the arrangements for the transit of milk, that traffic being under his charge. He was unable at the present moment to suggest any definite mode by which an improvement could be effected in the means of carrying milk from the provinces to London. The officers of the company wished to introduce small milk-cans, similar to those used in France. There were one of those cans now at Paddington, and he would submit it for the inspection of the Committee. The farmers objected to those cans, because they were air-tight. The milk was put into the cans warm, and they considered it necessary to have air-holes to allow the steam to escape. He thought it would be better to put the milk into the cans cool, and fill them up, so as to prevent the churning of the milk by the shaking of the carriage. Some farmers placed the cans in a stream of water to cool the milk after they were filled, and before they were sent away. He believed the milk was put into the cans, in France, in a cool state. He presumed the cans would be placed in water to cool the milk, as was done by some farmers in Wiltshire. The objection to the cans at present in use was their large size, rendering them inconvenient to handle. On the Great-Western line the sum of 2 pence per can was charged for taking back the empties, but the dealers objected to having cans of half the present size because it would add so much to the expense of the carriage of the empties.

The CHAIRMAN said at present that was not so much the question as the effect which the carriage in the larger or the smaller vessel had on the milk itself.

Mr. NICHOLSON could not speak on that point. The objection to the present large cans, holding nine to ten gallons, equal to eighteen imperial gallons, was the weight in loading and unloading, requiring two persons to lift them. The French cans were not more than half the size of the English. The milk was carried by the stopping passenger trains, and no trains had been put specially for that traffic. The milk trains were those which arrived at Paddington at 4.30 a.m., at 12.30, and 9.30 p.m. and 11.10 p.m. Each dealer sent his cart to the station for the milk he required. The way the trade was conducted was, all the milk that was sent up by the farmers was consigned to several wholesale dealers in London, who on its arrival sold to the retailers the quantity they required, and they took it away in their own conveyances, and he believed for the most part in their own cans, so that most if not all the cans that came up were emptied without being taken away from the station; they were then sent to the other side of the line and returned as empties. There was no competition for the milk amongst the salesmen at the station, the price being agreed to amongst themselves, and the whole quantity being consigned to them. It was not what could be termed a milk market at the station, as there would not be sufficient accommodation for that. Each salesman appeared to have his regular customers each day. The French milk van was like a narrow-gauge sheep truck with two tiers. He believed there would be great objection to a sudden change in the size of the cans, owing to the expense of providing new cans of half the size, as the present stock of cans was very large and would last for several years. He believed the milk cans now used would last for five or six years with occasional repairs. The French cans were made of stouter metal than the English, and in hot weather they were covered with a linen cover to keep the milk cool during the journey. He could not say whether the cans in France belonged to the railway companies or not, or whether the milk was distributed by them on its arrival. The principal supplies of milk on the Great Western Railway were from the neighbourhood of Swindon, Purton, and Cricklade, and that was the longest distance from which it was brought into London, being from 70 to 100 miles. Swindon was the principal station from

which the milk was taken. The effect of the cattle was to cause a larger quantity of milk to be sent the railway on account of the disappearance of the cows in London. The trade was not increasing at the present time, but rather the reverse. He attributed it in some degree to the competition of other railways. Large quantities of milk were brought up by the London and North-Western and the South-Western; also by the Great Eastern.

Mr. CHESTER—The railway which afforded the easiest facilities for this traffic would be likely to have the largest trade in that article.

Mr. NICHOLSON said the Wiltshire milk was esteemed for its excellent quality, and had a preference with many of the dealers. He was not in possession of any particulars with regard to the traffic in butter on the Great Western Railway. He regarded the question of the reduced size of the milk-cans as important, not only for the convenience of handling by the railway porters, but so for the conveyance of the cans from the farm to the station. The milk would be less shaken in cans of a size that a man could carry than in the present large cans, which were wheeled about on the edge of the bottom, and there would, he thought, be less damage to the cans themselves. There was no provision made at the stations for receiving the milk from the farmers beyond the cans being placed on the platform to await the arrival of the train that took them on. The change from the larger to the smaller cans would occasion great inconvenience to the traffic, unless it were done uniformly throughout the trade, and at once, as the same quantity of milk had to be carried whether it were carried in large or small cans, and a truck that would be adapted for the larger cans would not be available for the smaller size without great waste of space in the height of the truck. With two sizes of cans two descriptions of trucks would be required, and that would tend to obstruct the traffic rather than facilitate it. If the railway companies decided to insist upon the small cans being used entirely, it would be necessary to give the farmers and dealers at least three or four months' notice of that intention. It was quite necessary that the change, if adopted, should be general. The number of separate cans in use on the Great Western Railway, in the month of January, 1866, was 11,539. On an average there were about 500 cans carried to and from daily. The cans were of the value of about 32s. each when new. There would be, he imagined, somewhere about 2,000 cans in use in this trade on the Great Western Railway, as it was necessary for the dealers to have a reserve of cans. They generally put into each can only eight barn' gallons, but they mostly held nine gallons. He thought the reduction in the size of the cans would not reduce the rate at which the milk was carried on the railway, inasmuch as on the arrival of the train at the stations it was the rule for the milk dealers' men to assist in loading the cans, as it enabled the train to start away quicker. The French cans were of much thicker metal than the English, being something like galvanized iron; but if the English cans were made half the size, they would not require to be made so strong in proportion as the present large cans in use; and they were strengthened very much by tin hooping round them. They were from four to five feet in height, and not uniform. He should say the introduction of small cans would be a decided improvement in the milk traffic on railways. The milk brought up to Paddington was principally sold to about ten dealers, and there were thirty or forty retailers' carts ready to take the milk away on its arrival, after it was sold by the dealers. He did not think the distribution of the milk over London could be effected quicker than in that way.

The CHAIRMAN inquired whether Mr. Nicholson thought it would be too harsh a measure to give notice to all the milk producers that, after a certain time—say six months—no milk would be carried by the railway except in cans of a certain size?

Mr. NICHOLSON replied it might have the effect of driving the trade to another line from that which adopted that course. It was generally found that the railway which gave the greatest facilities for traffic got the largest trade. There were other railways which competed with the Great Western in certain districts. The South-Western was a competing line, and also the London and North-Western at Aylesbury, &c. The Great Western had the command of the district of Swindon, Purton, and Cricklade. If a decision were come to by the company to insist upon a smaller size of can being used, the notice, in his opinion, ought not to be less than three months; but it was a question whether other companies would consent to impose such restrictions. It would be an advantage to every company to have the smaller cans used, as they could be loaded and unloaded quicker. The great bulk of the milk brought to Paddington did not come from a greater distance than 70 or 80 miles.

Mr. LE NEVE FOSTER remarked that, according to returns sent to him, it appeared that the greatest distance from which it was brought by the South Western was from Wareham and Salisbury.

Mr. NICHOLSON added he thought it would be expedient to have special trains for milk if the trade sufficiently developed itself, and carriages had been specially fitted up for the milk trade on the Great Western line; old carriages had been converted for the purpose: but he thought, with Mr. Wood, that good would be done by the offer of a premium for an improved construction both of vans and cans for the carriage of milk. As he had stated, an admixture of large and small cans together would be productive of great inconvenience in the loading of the trucks. The milk trade to London had always been of an uncertain character, and had only sprung up on the Great Western line to any extent since 1865. A very large quantity was sent up last year, but at present it appeared to be falling off, and might continue to do so as the stock of cows in London and the neighbourhood increased. At present he did not see his way to any great practical improvement being effected in the milk traffic to London. No doubt the great increase in the quantity of milk sent up in 1866, was owing to the deficiency of the supply from London itself, and as the local supply was increased, the provincial supplies would probably decrease. The returns for the two months expired in the present year, showed a considerable falling off in the quantity as compared with that of the corresponding period of the previous year.

CANTOR LECTURES.

"ON MUSIC AND MUSICAL INSTRUMENTS." By JOHN HULLAH, Esq.

LECTURE VI.—MONDAY, APRIL 8.

MEDIEVAL INSTRUMENTS, &c.

After briefly alluding to some statements which he had made in his fifth lecture, respecting the different classes of instruments, Mr. Hullah proceeded to speak of the condition of these instruments, of the changes they underwent; and the additions that were made to them during the middle ages. The conquerors of the old world—the barbarians who broke up the Roman empire—found everywhere in the south of Europe specimens of ancient musical instruments, and artists skilled in the use of them. These remained in use for a considerable time. But the same influence which acted so strongly on the religion, politics, manners and customs of the south soon made itself felt on the arts. For our knowledge of mediæval instruments we are as much dependent on pictorial and plastic representation as in the case of those of higher antiquity; but happily, more of this representation has come down to us. Of the instruments themselves, few anterior to the 15th century remain. But for the notoriously irreverent spirit of the Renaissance, the

all but total disappearance of things made of such durable material, so strongly put together, and taking up so little room as many of these instruments, would be unaccountable. Few even of the beautiful organ cases of the best period of Gothic art have come down to us. Posterity however, has dealt with the Renaissance instruments as the Renaissance artists dealt with those of their predecessors. Specimens of some, no longer in vogue, of the 17th and even of the last century are hard to find. Who, for example, has seen a chest of viola, once an indispensable complement to a well-appointed household? Even the harpsichord is as unknown to the present generation as the shalm or the arch-lute. But if the instruments have, for the most part, perished, we have abundant evidence of what they were in the beautiful sculpture, illuminated books, and decorated walls and ceilings contemporary with them, and also in descriptions by the theorists, who wrote while they were in vogue. The diagrams on the walls were, Mr. Hullah said, selected from such sources, which were always thoroughly reliable; for no mediæval artist ever dreamed of leaving out what he saw, or putting in what he did not see, for the sake of effect. From mediæval monuments we learn that several instruments in use in the south at the time of the earliest immigrations of the northmen, were adopted by them; and that others, differing in form from these, and even indicating new methods of producing musical sound, were in use before painters or sculptors attained or recovered sufficient skill to represent them correctly. Among wind instruments the trumpet is most frequently found in representations of the manners and customs of the northmen. The first trumpet was, no doubt, literally a horn (*cornu*). In dimensions, these instruments varied considerably. Some were small enough to be held by the performer, others equalled him in height, and almost in bulk. Their pitch would of course vary with their dimensions. In timbre they probably resembled our trombone. In a MS. antiphonary of the 9th century there is a drawing (a copy of it was on the wall) of a trumpet in which the tube is folded back, and in which there is an indication of a slide, the characteristic member of the sackbut, the precursor of the trombone. Though the traverse flute was known even to the Egyptians, the flute-à-bec seems to have been used exclusively during the middle ages. Mediæval, like more ancient flutes, were single and double, and the same uncertainty prevails as to the tuning of both. Mediæval writers often include under the name *flute*, instruments which must have had more resemblance to the oboe; since they consisted, not of a single pipe, but of a pipe enclosing a vibrating tongue, or reed. Such instruments were sometimes distinguished as recorders. Of the flute there were in England in early times several different sizes, for playing in concert, the largest of which was probably six feet in length. The quality of these instruments must have been sweet, but their intensity very limited. In the reed instruments the tone was produced by the vibration of single tongues, or by the beating together of pairs of tongues. The former is the simpler, and probably the earlier form, the calamus, or typical reed of antiquity. Indeed the most important of mediæval single-reed instruments bore a name derived from that of its prototype. The word shawm, or shalm is obviously connected with the French *chalumeau*, the Latin *calamus*, and Greek *καλαμος*. The shawm, frequently mentioned in our translation of Scripture, was the ancestor of the clarinet, which, before the latter part of the last century, was a military or out-door instrument, as would seem to have been the shawm, and indeed all the reed instruments of the middle ages. So with the oboe, now essentially a concert instrument. The plays of Shakespeare abound in directions for the introduction of the oboe on the entry of great personages, and in battle scenes it is often coupled with alarums. In England the oboe was called also the wayte, a word applied to watchmen, part of whose duty it was to pipe the hours of the night. There was a considerable variety

of oboes—an oboe d'amore, and an oboe da caccia, the compass of which was nearly the same as that of the cor anglais, or corno inglese, still frequently used for obbligatos. But the favourite reed instrument of the middle ages was the bagpipe, which is many supposed to be peculiarly a Scottish instrument. This is a great error. The bagpipe, of immense antiquity, has been found among nations more remote, and, seemingly, more unconnected with one another than any instrument demanding the same skill in construction. It was known in ancient times all over the East, in Greece, and in every part of Western Europe. It has flourished, however, most in mountainous countries. The peculiarity of this instrument consists, not in the pipe, which is simply an oboe, but in its accompaniment by a pair of *bourbons* or drones. In the Scottish Highland pipe these are monotonous—the twelfth and fifth of its natural scale; but in the Calabrian pipe they are capable of some little variety. Another peculiarity of the instrument—that, indeed, from which it derives its name—is the bag, which is not generally a pair of bellows, but merely a receptacle for the breath of the player. Mr. Hullah then proceeded to speak of mediæval stringed instruments. The lyre appears in many monuments of the middle ages. In the first centuries of the Christian era everything associated with Paganism was avoided and repudiated by the Christians. The musical instruments of the old world, necessarily associated with Pagan worship, were regarded by them with horror; and even music itself must have run some risk of rejection. But the practical spirit which could adopt the Basilica as a model of the Christian Church, and, a little later, symbolise Christian truth by heathen fable, would not be long in turning to account an art said to have wrought such wonders in heathen times. The lyre, the embodiment and personification of ancient religion, poetry, and music, appears often in the illuminations and sculptures of the middle ages. Even as late as the thirteenth century its form was nearly the same as eighteen hundred years before. But, whatever the conquerors of the Old World may have learnt from it in other arts, in music they were competent to be rather teachers than learners, for they brought with them not merely instruments of the same principle and structure as those they found, but others unknown to the south of Europe, and, more than all, harmony, polyphony, music in parts—an art and science, acquainted with which or not the ancients never turned to account. Of the instruments brought in by the northmen the harp was the most important. Though probably known to the Romans, as it had been to the Greeks, it had never been adopted by either. How and whence the northmen got this instrument, is one of those historical or ethnological problems which will never be satisfactorily solved. It may have travelled from the East, across the north of Europe, or have suggested itself to such passionate lovers of music independently. Certain it is that the harp attained considerable perfection among our Anglo-Saxon, and even British, forefathers; and that both the instrument itself, and the art of performing upon it, were held in the highest honour among them. Moreover, harp is essentially a barbaric word. It appears, slightly varied, in Anglo-Saxon, Icelandic, Danish, and German. The Latinised form, *harp*, first appears in a poem by Venantius Fortunatus, who wrote in the 6th century; it is not to be found in any ancient Latin writer. Schoolboys are taught to render *cithara* by harp, but there can be no doubt that the guitar is the closer translation. The mediæval harp was a portable instrument, small enough to rest on the player's knee without hiding his face; an important point when he was not merely a player, but a singer and an actor, often a poet, who would address himself as much to the eyes as to the ears of his audience. Moreover, the nomadic life of the minstrel would have rendered a cumbersome instrument all but useless to him.

The pole or bar is a characteristic of the Gothic harp, which essentially distinguishes it from the Assyrian or Egyptian. The necessity for it originated no doubt in the different material of the string in the two instruments. The Egyptian strings were of vegetable fibre, silk or gut; the Gothic generally of wire. Gut strings, though known in the middle ages, were not generally adopted till the seventeenth century. Mr. Hullah then directed attention to several drawings of mediæval harps, among them the earliest extant, which is from a MS. of the 9th century, formerly in the monastery of St. Blaise, in the Black Forest; another, a quadrangular harp, also of the 9th century, to which the name psalter or psalterium is sometimes given. It is always found in the hand of David in MSS. between the 9th and 11th centuries, after which we find it replaced by the harp proper. He also exhibited drawings of psalteries of the triangular form in use from the 12th to the 16th century. The origin of this instrument was said to be eastern, and the name to be derived not from the Greek *ψαλλω*, to sound, but from the Arabic *santir* or *psantir*. A similar instrument is still in use in the east, but the strings are struck, not, as in mediæval Europe, plucked. Though not so picturesque as the many-stringed instruments, stopped instruments—those having finger-boards—are incomparably more important; not so much in themselves, as in their closer connection with the violin species, the use of which has so enormously influenced modern music. The finger-board, as was shown in the last lecture, is probably three thousand years old; but the most ancient western monuments of its existence are not older than the seventh century. It has been thought that the guitar species disappeared from Western Europe for some centuries, and was re-introduced with the Crusades. The mediæval *cythara* was not a guitar, but a harp. Stopped instruments are of two forms:—(1) with rounded pear-shaped backs, (2) with flat backs. The type of the first form is the *lute*; of the second, the guitar. The invention of the latter is generally attributed to the Arabians. Its Arabic name is *coud*, which, by the prefixing of the article has become *laoudo* in Spanish, *lauto* or *luto* in Italian, *luth* in French. Mr. Chappell, with characteristic patriotism, derives it from the Anglo-Saxon *hlud* or *lud*, i.e., sounded. Once the most popular of domestic instruments, the lute has been superseded by its inferior relative, the guitar, which, in its turn, has greatly declined in general use and estimation. Mr. Hullah then called attention to two drawings of the *mandora* (whence the more familiar *mandolin*), a species of lute, and a small Moorish instrument of the same kind; and two so-called *Latin guitars*, one of which presented the nearest approach that an instrument could make to a violin without being one. It had sound-holes, sides indented, or *échancrés*, and apparently a bridge. In conclusion, he announced that he had been invited to conclude his course (which he had found impossible in the time prescribed) by giving two additional lectures, on the 29th inst. and the 6th May. In these he proposed to deal with the instruments of the violin species, and the combination of wind and stringed instruments in the modern orchestra.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 10th, 1867; CLIFFORD WIGRAM, Esq., in the Chair.

The following candidates were proposed for election as members of the Society:—

Bailey, John, 163, Oldfield-road, Salford, Manchester.
Blacklock, William, J.P., Hopefield, Pendleton, Manchester.
Burton, Oliver, Tyldesley, near Manchester.
Henson, Henry H., Rutland-lodge, Watford, and 13, Parliament-street, S.W.
Sandbach, Wm. Robertson, 10, Prince's-gate, Hyde-park, S.W.

AND AS HONORARY CORRESPONDING MEMBER,
Nobile, Signor Commendatore Gaetano, 14, Via Salata, ai Ventagliari, Naples.

The following candidates were balloted for, and duly elected members of the Society:—

Cassels, Andrew, Manchester.
Eadie, Robert, Blaydon-on-Tyne.
Mendel, Sam, Manchester.
Pagan, John T., J.P., Oak Lodge, Guildford.
Rydon, Horace James, Pyrland House, Highbury New-park, N.
Tolhurst, John, 152, Tooley-street, S.E.

The Secretary called attention to a new form of portfolio stand, or table, invented by Mr. McLauchlan. For description see page 333.

The Paper read was—

ON THE OPERATION OF THE CHAIN CABLES AND ANCHORS ACT, 1864.

By ROBERT GALLOWAY, Esq., C.E.,

Chief Surveyor of Steam-ships, and Examiner of Engineers; and Inspector of Proving Establishments, Apparatus, and Machinery.

The two questions that I propose to discuss this evening are:—

1st. Is the test rendered compulsory by this Act a proper test? and,

2nd. Is it sound policy for the Government to institute any compulsory test?

The Chain Cables and Anchors Act, 1864, which is a fair specimen of that class of legislation that does at once too much and too little, is known as an Act for regulating "The Proving and Sale of Chain Cables and Anchors." It received the Royal assent on the 23rd June, 1864. It was passed, as stated in the preamble, on the grounds "that it is essential for the better security of lives and property afloat on sea-going ships to make provision for the proper testing of chain cables and anchors."

With the view of ensuring this "proper" test of chain cables and anchors, it provides: "That any corporation, public body, company, person or persons erecting any proving establishment, apparatus, and machinery suitable for testing chain cables and anchors, may be licensed by the Board of Trade." The Board of Trade have power to appoint an inspector of proving establishments, and "may" license any establishment which that inspector certifies as being suitable for testing chain cables and anchors under the Act. These licenses are renewed (after inspection) annually.

Here we have all that is required of the Government and their inspector. It is well that we should understand this point at once and thoroughly. The inspector is required to inspect the establishment, apparatus, and machinery. If and when he is satisfied that it is suitable for testing chain cables and anchors, under the Act, he gives a certificate to that effect, and has done with it—unless and until the owner wants his inspection again next year. The inspector merely inspects for sufficiency once a year, and his duties and powers end. The duty of the Board of Trade is simple enough. It is defined in a very few sections. It has power to appoint an inspector; to charge fees for licenses; to grant and renew licenses on receiving certificates from the inspector; to remunerate the inspector; to approve of proof marks; to fix a scale of charges for proving—and that is all. In short, as far as the Government are concerned, it has had to settle the scale of fees; to approve of the proof marks, and to determine the conditions necessary to be complied with by proprietors of proving establishments to satisfy the Inspector that a machine can exert the strain required by the Act. Having done this the Government are not required, nor are they authorised or em-

powered, to do anything more than issue certificates annually on receiving reports from the Inspector.

The next thing for us this evening is to understand the duty imposed on the tester. It is his duty to see that chain cables and anchors which may be brought to him for the purpose are "tested" in their proper turn, and if they stand the test then he is required to stamp every five fathoms of chain and every anchor to denote that they have been "proved." The tester has a right to certain fees for testing, and has power to detain the property until those fees are paid. He is also required by the Act to give a certificate of proof, free of charge, within one month after a cable has been tested.

Any persons improperly stamping, or assisting in stamping a chain cable, &c., or counterfeiting proof marks, are liable to be punished, if it can be proved that they have done so for the purpose of, or with the intention of, passing it as a chain cable, tested and stamped under the Act; and any person giving a certificate of proof, under the Act, for a cable or anchor that he knows has not been proved is also liable.

The chances of conviction, under this clause, depend on proving the "intention" of the fraudulent marker, the "knowledge" of the fraudulent seller, and the "knowledge" of the forger or issuer of certificates for untested chains and anchors, and on proof being produced that the chain is supplied to be used as part of the equipment of any ship or vessel. As regards the seller and dealer in anchors and cables, the Act provides that it shall not be lawful for any maker of, or dealer in, chain cables or anchors to sell or contract to sell "for the use of any ship or vessel" any chain cable whatever, or any anchor exceeding in weight one hundred and sixty-eight pounds, unless they have been tested and stamped under the provisions of the Act; and any person selling a cable, &c., fraudulently marked, and knowing it to be so wrongfully stamped, is to be punished. So that to get a conviction it is necessary to prove first that the anchor or cable is supplied for the use of a certain ship or vessel, and secondly, the knowledge of the fraudulent seller.

The last clause, and one which the opponents of the Bill look on as the best clause of all, provides that the Act shall not remain in force beyond the 1st February, 1872.

To sum up, the Act requires all cables, and all but very small anchors, to be tested at a machine licensed by the Board of Trade. That machine may be the property of an independent corporation, or of a manufacturer. A tester may test his own cables and anchors, on his own works at machinery of his own, and by his own workmen, and then himself give a statutory certificate of public proof. The Act provides for an annual inspection, and an annual licensing of machines, and imposes penalties on persons not complying with its provisions. Is not this at once too much and too little?

We have seen what the Act does provide for, and we will now see what it does not provide for, or, if it provides for, does not secure. The Act does not empower any person or department to see that its provisions are complied with. The Board of Trade have no power or authority whatever to prosecute for offences under the Act, and have no funds at their disposal out of which to institute prosecutions, and the manufacturers, and buyers, and sellers of chain cables will not prosecute. It of course rests with persons aggrieved to take steps for themselves, but they have not done so yet. No provision is made for punishing any person who tampers with a proving machine after it is licensed by the Board of Trade. The Inspector gives his certificate when he is satisfied that a machine can do a certain amount of work if fairly and honestly used, but any one can alter that machine after it is licensed so as to make it exert a lighter strain than intended. It should therefore be unmistakably understood that at present the Board of Trade license is only a guarantee that the machine can

do a certain amount of work, but is no guarantee at all that it will be required to do so, or that cables tested at it will be tested to the strain required by the Act, or at all be tested to any given strain.

The Act does not insure an independent test. However honest a man may be, he ought not to be allowed to test his own articles for certificates of public proof, and, without in the slightest degree impugning his honesty and integrity of any person, one may fairly say that so long as a maker, be he ever so honest, is allowed to test his own chains for a statutory certificate of proof, the Act is not satisfactory.

But assuming, as is without doubt the case, that every establishment licensed under the Act is honestly worked, whether public or private, whether under separate management, as at Birkenhead, or at Lee Walker, or whether in the premises of, and under the sole control, guidance, and management of, the manufacturer himself, the question still remains whether the test required by the Act is itself the proper test. We must now consider what that test really consists of, and for this we must refer to the Act,—Section 1. The section provides that—"Every tester shall, with a reasonable despatch, subject every chain cable or anchor that shall be brought to the proving establishment of such tester for the purpose of being proved, and which the parties interested may otherwise agree) in the order in which such chain cables and anchors respectively shall be so brought, to the same tensile strain as that to which chain cables and anchors respectively of similar weight, or description are or shall be subjected before being received for the use of Her Majesty's naval service." From this it will be seen that the only test required by statute is a "tensile strain," or, in other words, a direct pull of a certain amount, varying with the size of the chain.

Having seen that the only test is a direct "tensile strain," we must next notice that that "tensile strain" is not regulated by the quality of the iron of which the chains are made, but solely by its thickness. In other words, the test as it is now applied, is applied on the false assumption that strength and thickness are convertible terms, or in other words, that iron of a uniformly good and high quality is used in the manufacture of the cables.

Authorities on the subject of the strength of iron and iron work lay it down as a rule that the proof strength and working stress should bear a certain fixed proportion to the ultimate strength and to each other; and that these proportions can never be departed from without risk. Now, assuming (without admitting or denying) that the proof or Admiralty test legalised by the Act we are now considering, is, or was, determined by, and bore a fair and proper proportion to, the ultimate strength of the material used at the time for cables, and that that test was the proper test for the particular quality of iron of which chains were made when the proof was established, does it follow that it is the proper test now?—and the best for all sorts of iron, whatever their quality? Does it not rather show that it is only a proper proof for the iron of the quality for which it was established? And is it right now to apply this proof indiscriminately to all sorts of iron, bad or good?

To make my position clearer. We know that when a minimum scale, or quality, or size, or proof is fixed by the Legislature, that minimum very soon becomes the practical maximum; that when a standard of minimum strength or thickness is once fixed it is worked up to, and so long as that minimum strength is arrived at, or that thickness attained, the Act is complied with, and the article or building passes muster, and gets a certificate, without reference to other and perhaps more important considerations. Now it so happens that iron manufacturers and chain cable makers are the cleverest people in the world for producing an article that will stand a certain test. It is no part of

business of the manufacturer of cables to ascertain the ultimate strength should be so much more than proof strength, and the working stress so much less. He has to do is to comply with the provisions of the Act and to take care that his cables will stand the proof, he can do this to a nicety.

Professor Rankine, in his work on applied mechanics, says:—That for wrought iron boilers the proof strength should be half of the ultimate strength, and the working stress one-eighth of the ultimate strength, or one-fourth the proof strength. As regards wrought iron, for ordinary loads, that the proof strength should be half the ultimate strength, and the working stress should be one-third of the ultimate strength. We see that proof strains should bear a certain proportion to the ultimate strength and working stress of the material proved, and as the Chain Cables Act does not provide for this, such a test in the case of chain cables is fundamentally and radically wrong. The manufacturer may make a chain that will stand the proof, but it will break at 10 per cent. above it. In this case the ultimate strength is only 10 per cent. more than the proof, instead of being, as it ought to be, far more. In such a case the iron is tried beyond the limits of elasticity and the cable is ruined, and it is rendered but poor weak thing, ready to part on any sudden stress or strain being applied.

The answer then to my first question, whether the test required by the Act is a proper test, is that no test can be a proper test that is not regulated by the ultimate strength of the material tested, and that as the test required by this Act is not so regulated, it is not a proper test.

The second question for consideration is, should there be a compulsory test?

The result of the working of the present Act is stated, in papers presented to Parliament, as follows:—

Messrs. Lamport and Holt to the Secretary of the Board of Trade.

Liverpool, 11th February, 1867.

SIR,—We venture to take the liberty of calling your attention to the unreliable character of certificates of the testing of chains and anchors given under the provisions of the Act of Parliament. Confining ourselves to our own experience, and beginning with the month of November, 1865, no less than seven cases have occurred of the breaking of new and duly certified chain cables in use on board steam vessels of which we are owners. In all these cases the certificates were such as would comply with the requirements of the Board of Trade surveyors. The latest of these cases, that of the screw steamer "Donati," which happened in the river Mersey on the 8th inst., affords means for minute inquiry into the circumstances, in the event of your considering the subject sufficiently important for such an investigation. This steamer was supplied with two cables, 150 fathoms each, of 1½ inch chain. A copy of the testing certificate is enclosed herein. Both cables broke successively, almost immediately after the anchors were dropped, and while there was but little strain upon them. One of the cables had never been used before; the other had been used only once before. We may be forgiven for adding that so many cases of broken chains had not occurred to us in our previous twenty years' experience as shipowners.—We are, &c.,

(Signed) LAMPORT AND HOLT.

J. J. Lawrie, Esq., to the Secretary of the Board of Trade.

Glasgow, 16th March, 1867.

SIR,—As it is probable that measures will shortly be adopted to amend the Merchant Shipping Act, 1854, I am anxious to mention to you the following matter of an analogous kind, and of great interest to the shipping interest. Since the Chain Cables and Anchors Act, 1864,

came into operation, by which the chains and anchors of ships must be subjected to certain proof strains, defined in that Act, before they can be used on board ships, the number of accidents caused by the breaking of the cables has been very much greater than before the passing of that Act. I am certain that I understate the facts when I say that for one case before the passing of the Act in which the cables were broken in the riding of the ships, there have been ten such accidents since the Act came into operation. The inference that has been drawn from these accidents is, that the cables are heart-broken in the process of being proved, and that the Act either requires too great a proof strain, or is defective in not providing that the iron of which the cables are made shall be of a quality that will sustain, without injury, the specified proof strain. This feeling is becoming so strong that for the safety of the ship it is now considered very undesirable and unwise to subject the rigging chains to a proof strain so great as that specified in the Act for cables. It is certainly most important that cables and anchors, and indeed all the chain used on board ships should be proved to be well made and of good iron, but for that purpose other means, I humbly submit, should be employed than those specified in the Act.—I am, &c.,

(Signed) J. J. LAWRIE.

Now, without endorsing these statements to the fullest extent, there is, I think, abundant proof that the test imposed by the Act has been the means of introducing inferior iron more generally into use than formerly. I do not say that this would be the result of a proper test, but I think that it is the result of the present test. It may fairly be admitted and assumed that a proper test and a proper examination are necessary, and that the aim and object of the Government should be to ensure such a test; and it cannot be denied that no cable or anchor ought to be used on board a ship, or insured by underwriters, unless and until it has been properly tested, examined, and certified. We cannot give Mr. Laird and the promoters of the Bill too much credit for their philanthropic designs in trying to get a proper test. Here we shall all agree, but the question is—how should that proper test and examination be secured? Here we are likely to find a difference of opinion. There are some persons who would wish the existing Acts to be made more stringent, to give the Government further powers of supervision and inspection, and powers to prosecute and recover penalties. There are even some who would go so far as to make it felony to sell an untested chain. On the other hand, there are those who are for doing away with the compulsory test entirely, and for giving buyers and users an easy and effectual remedy against sellers of bad chains.

To speak broadly, there are two opposing parties:—the one wish the Government to do all the work of supervision, and to take all the responsibility; and the other wish the Government to take their proper place as chief policemen, and to leave the responsibility where it ought to be left—on the shoulders of the persons most interested, viz., the buyers, users, and sellers of cables, and the public. Those of the former school are a very numerous class, and those of the latter school include men of careful habits of thought.

Our object to-night is to raise discussion; I propose, therefore, to take the side of the opponents of undue interference on the part of the Government. In a hall like this, where men of intellect, and capable of reasoning "most do congregate," it is well to raise a direct issue, and to have an argument. It matters little whether the person raising it is right or wrong. The great point is to raise an issue, and to invite discussion, so that, through that, we may arrive at truth. I then—with this object in view, as well as from firm conviction—will say, that a compulsory test is bad and vicious in principle, and should not exist; and I call on

any person opposed to this view to express his opinion openly, and to controvert it.

After raising this direct issue, I have but little to do before sitting down and listening to the opinions of those gentlemen who may favour us with a statement of their convictions and conclusions, and of the grounds or process on and through which they have arrived at those convictions and those conclusions. I have only now to say that I think that public security would be ensured, and the objects of the promoters of the Act would be gained, if public corporations alone were allowed to test chain cables for certificates of public proof. I would, however, not have that proof compulsory, but would have it more effectual than compulsory proof. I would make it to the interests of all parties concerned to use good iron and good workmanship; and I would, as Mr. Gray stated, in his paper, read in this room in February,* 1866, and, as I believe, had already been suggested by the Board of Trade, do this simply by authorising the Board of Trade to licence public machines, and regulate the nature and extent of the test, and then leave it for the buyer to have his chain tested at a public machine, at the expense of the seller. We should have then but few bad chains; and it would be to the interest of all persons to make, provide, sell, underwrite, and use good chains without the assistance of any compulsory legislation at all.

Unless something is speedily done, we shall, according to opinions pretty frequently expressed, be placing our merchant ships in a far more dangerous position than they were before the passing of the Act.

Gentlemen, I thank you for the attention you have given me, and call on you to express your opinions in a plain and unhesitating manner.

DISCUSSION.

The Earl of CAITHNESS said he looked upon the question brought before them by Mr. Galloway as one of vital importance to the country at large, and, indeed, to every country in any way interested in maritime affairs. He did not like to say he was positively against it, but he certainly was not much in favour of the compulsory testing of chain cables. At the same time he thought it was very important that a chain cable should be tested, because, as every link was welded, it seemed necessary that there should be some means of ascertaining whether every weld was perfectly good; but to test a cable to anything near its breaking strain was, in his opinion, a great mistake, because then the ship had nothing left to do but to break it, and when a ship was lying in bad weather, they all knew that the strain was not of the most gentle or even character. The cable would not stand such a strain as that when it had been half broken previously, all the elasticity of the iron being destroyed, the fibres being torn, and, he might almost say, disintegrated. He was afraid, also, that the best material was not usually put into chain cables at the present time. John Bull liked to put a shilling into his pocket when he could, as well as anybody else, and he did not blame him for doing so, but when it was a question of life and death, and of such a vast amount of property, as was involved in the safety of a ship, the very best material ought to be used. He would urge upon any one who had anything to do with shipping not to have his cables tested to anything like the breaking strain. Not being himself an engineer, however, he offered his opinion with some diffidence.

Mr. BETTERLEY said that he should like, having been connected with the making of chains and anchors for the best part of his life, and having made the largest anchor in the world for the Great Eastern, to give the result of his experience. The first question was, whether the testing of chain cables should be compulsory or not, and, as far as that was concerned, if there were such a

thing as a proper test he would readily agree to it; but the fact was, that all the Act had effected was not a government proof of the chain cables themselves, but only of the machinery for testing them. Some of these machines were examined to such a degree of nicety that they would almost prove a chronometer, and the expense the country was put to in consequence was enormous, whereas he (Mr. Betterley) could put up machinery for £150 which would test any chain cable, because nothing was wanted but a hydraulic press. Then came the question, who was to examine the chain and give a certificate respecting it. It was true that a government inspector had passed the machinery, but his duty did not extend to the examining of cables. The person who did this had no certificate of competency; he might be an engineer, a chain maker, or, indeed, anything else; anyone who was well recommended might get such an appointment, which was worth perhaps £3 per week. Some firms paid as much as £50 a week for proving, and it would be well worth their while to pay an additional £5 a week to get their cables passed. The present compulsory test really involved an expense of about £1 per ton, for there was not only the expense at the proof-house, but the carriage to and fro, and this amount was really so much taken from the value of the iron which was put into the cable, so that in fact people got worse cables for their money. Cables had been proved and certified in Staffordshire, and when they went down to Liverpool they had been found to break. The certificate said that the cable had been proved to a certain point, and, as Lord Caithness had well observed, the ship had often nothing left to do but to break it. But not only did this law add £1 a ton to the cost of the cable, but it led to the manufacturers getting a Government certificate for their "proof-house," whether or not it was rightly used afterwards. This was just like building a stable, and getting an architect to certify that it was properly erected, but having no certificate as to the soundness of the horse it contained. As to the welding of the links, they did not require any Government inspector for that. He maintained that the machinery for trying the men's work, whether it were sound or not, was as much a portion of the machinery of the shop as anything else in it. It was the business of the master to ascertain whether the work was sound, but if they were to go further, and seek to ascertain if the iron were good, they must pull the chain to pieces, and if that kind of proof were required all the cables would be destroyed. He was in favour of the cables being tested by some person thoroughly competent to examine them, who should be allowed to take out two or three links wherever he thought proper, and strain them until they broke. Then he could give a certificate that the iron in such a cable stood such a test, and if it did not stand 50 per cent. more than the present proof he should not give a certificate at all. He thought that by such means they would get good cables. All this was a matter of indifference to some classes of shipowners; in fact, there might be said to be a premium offered to them against good cables, because, in many cases, they could recover more from the underwriters than the value of the vessel. There were many cleverer swindlers than the man Houldsworth, who bored a hole in his vessel; many a clever scoundrel would prefer to buy a cheap cable, that did the business quite as well as the auger. Therefore, it was a serious question for the underwriters to consider, whether they would insure chain cables at all, so that if a ship broke her anchor or chain they would not hold themselves liable, or, at least, would reserve the right to deduct so much from the insurance. That would make it a necessity with the shipowner to provide good ground tackle. The whole value of a ship, perhaps half a million, often hung on a chain with a thousand links, and the weakness of one would destroy the whole. It was the interest of the underwriter to look after these things, and the question then arose whether the Government should step in and protect the underwriter, or whether the underwriter should protect himself.

Mr. T. M. GLADSTONE said the subject before them had long been familiar to his mind, and he was one of those who had taken a part in bringing about the present Act. The question now raised, whether the test provided by that Act was a proper one, he would himself answer in the affirmative. This kind of test had long been used in the Admiralty dockyards, and when it was found that the cables supplied to the Royal navy were fifty per cent. better, at the very least, than those generally used in the merchant service, he thought it might be considered a fair argument that a compulsory test, whereby the same high quality should be secured in chain cables generally, would be a step in the right direction. This test indicated something like two-thirds, or less, of the strength which might be expected from good material, so that there was sufficient margin left, provided that the material was really good. The test applied rather to the manufacture—to the weld, which was the weakest part—than to the material itself, and was thus efficient when good material was used; but still manufacturers could contrive to make an article which would just pass the test and nothing more, by employing inferior iron. Still he maintained that, although this might be the case, experience under the Act had shown that upon the whole we now got better cables than before the Act was passed; for, before that test was enjoined, seven-eighths of the ordinary chains would not stand the test at all by 15 to 20 or 25 per cent. He perfectly agreed, however, with the suggestion of Mr. Betterley, as to the taking out two or three links at the choice of the inspector and subjecting them to an additional test, which if they did not stand, the cable should be rejected. Some test should be used quite beyond that which related to the manufacture. No chain should be allowed to be used which would not stand at any part selected from 25 to 50 per cent. additional test. An allusion was made in the paper to the striking difference in the testing of boilers. If boilers were made as chain cables were, merely to be equal to the proof test, there would be no security for the quality of the material, and the test would be very imperfect, and therefore he believed the conditions imposed were that the plates themselves should stand a certain pressure to the square inch beyond that to which the whole boiler itself was subjected. Why could not the same principle be adopted with chain cables? A person who understood the manufacture of iron would, without testing a link at all, by simply breaking it to pieces under a hammer, know from the nature of the fracture, whether it was made of common, inferior, or good iron. That would be a good way to test the material used. The next question was that of general examination, and this could not be too perfectly performed. The Act of Mr. Laird, however well intentioned, was nevertheless defective; tending in a great degree to produce the result given in the letters which had been read. Still he was of opinion that there should be a compulsory test, because if it were left to the manufacturer there would be little or no test at all. Even now thousands of cables had gone out with certificates that never were near a testing machine at all. Then the next question was, was it sound policy for the government to provide a proper test? He most distinctly considered that it was. It had been left to private parties, and they had altogether failed in providing what was required. Lloyd's Committee, for which he had the honour for some years to be engineer, took great pains, before the passing of this Act, to establish public tests; and at first, before the manufacturer contrived to reduce the quality of the material, there was a great improvement in the chains produced; but, after a time, it was found that there were no means by which the quality of iron could be properly tested. He thought the Act could be amended as to secure that protection which the public had a right to demand. In the proof at the dockyards, the quality of the material was examined beforehand, and the want of this additional precaution was the worst defect in the arrangement under Mr.

Laird's Act. He had formed these opinions from long experience in this matter, and he hoped that some suggestions would be made and adopted, which would secure the desired object.

Mr. G. B. GALLOWAY said he perfectly coincided with the views of the preceding speaker. It seemed a great anomaly that an inspector was appointed only to test the machine. He quite agreed that this was an underwriter's question, but it was a national question also. He did not think it would be sufficient to take out two or three links in order to test the quality of the cable, because the blacking and swaging covered up little defects in the welding which might pass unnoticed if the whole chain were not tested. He was of opinion that the importance of the question demanded a compulsory test, that a proper test could be devised, and that there never would be a proper test, except under Government inspection.

Mr. BRASLEY (of Liverpool) said although he thought the present Act did not now work satisfactorily, he was yet of opinion that it was quite capable of amendment. Several of the previous speakers had suggested the remedies, and he believed the noble lord who opened the discussion was right in saying that a great deal of the present breaking of cables resulted from the overstraining to which they had been subjected. Within the last twelve months he had had the cables of a new ship tested at the Birkenhead works, where there was admitted to be the best testing machine in the country. The ship he alluded to sailed in May last for Calcutta. She first of all parted one chain in Calcutta, and then she came back and anchored in the Downs, and there she parted the second. He had a piece of the broken link in his hand, and, as Mr. Gladstone had said that he could tell by looking at the fracture what was the quality of the iron, perhaps he would kindly say. The explanation of the cable-manufacturer was, that as shipowners, when they had a contract, sent round for the lowest tenders, the manufacturers went in for the lowest quality of iron that would bear the strain. He, in his simplicity, had always thought that when he had a cable which had passed the Admiralty test it would be capable of bearing any strain which was likely to come upon it. The present Act seemed, therefore, a mere delusion, especially as it now appeared that the Government did not themselves certify to the cables, but only to the machine, which he believed was contrary to the impression of most underwriters. Here were two cables which had gone through the very best machine, and they both parted the very first voyage.

Mr. T. M. GLADSTONE asked whether the cable broke in the iron or in the weld.

Mr. BRASLEY said it had gone both in the iron and in the weld. Mr. Brasley then read a letter which he had received from the Inspector at the Birkenhead works, which, after describing the way in which the writer identified the cables, stated that one of the cables broke four times during the test, and had eleven other defective links, and the other one broke once, and had one other defective link; both were repaired on the premises, and were then re-tested. The following were the strains at which the links parted, which went to show that what had been stated, as to manufacturers calculating to a nicety, was correct:—The first link broke at 58 tons 15 cwt. in the iron (the admiralty-test being 59, so that it came within 5 cwt. of it); the next broke at 58 tons 14 cwt. in the iron; the next at 57 tons 15 cwt. in the iron; the next at 58 tons 5 cwt. in the weld; so that only one of the four faults was in the weld. The second cable broke at the exact strain of 59 tons. He thought the Act required a great deal of amendment, but he still was of opinion that compulsory testing should be continued.

Mr. T. M. GLADSTONE said the broken link which had been handed to him had been about half welded. It was perfectly clear that iron of that quality, if thoroughly welded, would have left a considerable margin of strength above the test. There were two conditions

a defective weld. A link might be half welded, or it might be over-heated, and the quality of the iron thus destroyed at a particular part, although the general character of the material might be good. The only guard they could have against these evils was an examination by an independent person. There should be a full examination of the chain, and also of the material before it was used. Those were the only securities they could have, for it was impossible, under any law, to obtain positive certainty in this matter, in the same way as they could arrive at the absolute purity of gold or silver.

Mr. JONES asked if it were ever noticed that a change in the form of the cable resulted from the testing of it, and if this were not followed by a diminution of strength.

Mr. BETTERLEY said his experience showed that if a chain were tested beyond a certain extent, if the iron were good it was drawn out, and it became smaller than it was before. If it were struck with a hammer while under this strain, it would go to pieces.

Mr. JONES asked if it were possible then to subject a chain to a proper test without disturbing its form.

Mr. BETTERLEY did not think it was possible to apply a test of any value without so doing. They might try it to a certain extent in order to try the workmanship, but the moment you began to try the character of the iron, that moment you began injuring it. He was therefore an advocate for a moderate test to try the workmanship, with liberty to take out two or three links at any part in order to try the quality.

Mr. JONES doubted whether there would not even then be a risk of some of the links being made of inferior material. He knew this was the case in gold chains; it was not safe to assay only one or two links.

The CHAIRMAN said his own opinion on that subject, both as a shipbuilder and shipowner, was decidedly opposed to the compulsory testing of anchors and cables. Firstly, on the principle that you could not make people moral by Act of Parliament, and, secondly, because he did not see why anchors and chains were to be the sole portion of a ship's outfit which was to be tested. They were important articles, no doubt, and occasionally the safety of a ship and of everybody on board depended on their strength, but why were they to be tested and not the rigging, masts, yards, and sails, on which that safety much more often depended. Whenever a ship was in deep water, and exposed to the full fury of the winds and waves, perhaps in a hurricane, her safety depended on her inherent qualities as a good ship, on the strength of her masts and rigging, and, more especially, on the strength of the main post of the rudder. He thought it was very unwise to legislate on one portion of a ship's outfit and not on the rest. His own experience of anchors and chains was that there was not the least difficulty in getting sound and good ones by any shipowner who would pay a good price. If they went to the very lowest market and paid 10s. to 10s. 6d. per cwt., they could not expect the same article as if they had paid 12s. When a man's name became known as an owner who provided his ships properly, the underwriters would have confidence in him, and would often be willing to underwrite everything on board at five per cent. less than they would in other cases, and in consequence he would perhaps be able to charge 2s. 6d. a ton larger freight. One practical result of the introduction of the Admiralty test was this:—They used to have what were known as Admiralty chains and merchant chains, and the merchant chains were required by the Lloyd's Society of Underwriters to stand a certain test which was much lower than what was known as the Admiralty test. If shipowners were willing to have their chains made of a superior quality, so as to stand the Admiralty test, they were allowed to use smaller chains than if they only stood the merchant test. The practical working of the present Act was that smaller chains were used, so that although they might be

of superior quality, they would not stand a greater strain than they used to do when they were larger but of slightly inferior quality. In his own mind he was convinced that the piecemeal legislation, which referred to only one portion of the ship's outfit, was objectionable, whilst it left everything else to the discretion of the owner. He begged to move a cordial vote of thanks to Mr. Galloway for the important paper he had read.

Mr. GALLOWAY begged to thank the meeting for the patience with which they had listened to his paper, and also those gentlemen who had been kind enough to offer the remarks which he had been very much pleased to listen to. It seemed to be the general opinion that the law required amendment, and the only question was what the amendment should be. That must be very well and carefully considered, and he hoped that with the assistance of shipowners and others interested, a proper decision would be arrived at.

PARIS UNIVERSAL EXHIBITION.

Great advances have been made since the opening day, and those who desire to study the whole exhibition cannot do better than commence at once, before the public begins to throng the galleries; but this period will not be a long one, for now that the admission is only one franc, the stream will soon become large and constant.

The picture and sculpture galleries are more nearly complete than any other portion; the works were all hung, and the floor covered on the opening day, and on the day following the labels and numbers were being placed on the frames. In the French and other sections the walls are all, with very few exceptions, covered, and the same process of labelling is now going on there. The collection is an extremely fine one, especially as regards France, Russia, Germany, and England; the special galleries of Belgium and Holland in the park were not opened two days ago. The total number of works of art is very large, perhaps five thousand in all, without including the contents of the retrospective portion.

As regards the latter department, the French and Russian sections are the most forward; in the former there is a small but curious collection of ancient arms, bronzes, iron work, carvings in ivory and wood, all in perfect order. In the French section the cases are all ready, and are being rapidly filled; the show of enamels, carvings, faience, iron work, and furniture is highly interesting, and promises to be very fine.

The English section of this gallery has been delayed by the fitting of a double-iron door, to prevent all chance of accident by fire; but, from what we have already seen of the promptitude exhibited by the commission, our retrospective gallery will very soon be complete.

With rare exceptions, the weather during the past week has been fine, and the effect on the park and garden is astonishing; the paths are now in fair order, the shrubs are budding forth, and the Paris gardener, from his immense stores, can fill the flower-beds at any moment as soon as the cold winds warrant his doing so. What the trees and shrubs are covered with foliage, the objection, somewhat captiously made, to the heterogeneous appearance of the park, will be almost entirely removed. But without any qualification or alteration the park presents a mass of most interesting novelties teeming with instruction for those who are inclined to study.

There is in the park a model crèche, where infants may be left by mothers visiting the exhibition; those who have the welfare of the working classes at heart, and especially those who reside in manufacturing districts will do well to examine this simple but useful philanthropic establishment.

Men of business will be glad to know that the post and telegraph offices in the park are now in full operation, the regulations of the former are the same as at the present

dipal district offices in the city; that is to say, letters can be posted till a quarter to six, or with additional stamps of 20 cents, or 40 cents, till six, or a quarter past six. As regards telegrams, notice is given that the country and class, or section, must be added to the name of the exhibitor, or his agent, to insure delivery.

The special railway laid down for the purposes of the Exhibition is opened to the public, and promises to answer its purpose admirably. As already stated, it connects the Exhibition with the circular line around Paris, as well as with the terminus of the Western Railway, which is situated in the English quarter, not far from the church of the Madeleine. The trains at present run to and from the latter point every hour, and the journey occupies half an hour. The carriages are all of the second class, and the fare 50c. for the whole distance.

The Corps Legislatif has adopted the proposed law for the security of inventions and improvements; all those who exhibit anything which they desire to protect, whether mechanical or artistic, must comply with the regulations and forms of the patent or registration office in Paris within the current month, but no fees are charged by the Government.

The International Juries have commenced their labours, and, considering the time allowed, and the great extent of the collection, exhibitors should take care that all necessary facilities and information should be afforded to the juries, whose time is exceedingly precious; the British Commission has appointed a delegate in each class, to act as intermediate between itself and the juries, and thus protect the interests of British exhibitors as far as possible, but it depends upon the exhibitor to furnish the necessary information, and to see that his name, number, &c., are properly given. It may be well to mention that the delegate has nothing whatever to do with the appreciation of the objects; this rests entirely with the juries.

M. Walowski, the learned professor, member of the Institute of France, drew the attention of the students of the Conservatoire des Arts et Metiers, to the Exhibition, the other day, by a lecture on the History of Industrial Exhibitions. M. Levasseur, professor of history at the Lycée Napoléon, has also delivered a lecture on the same subject at the Sorbonne.

POSITION OF INVENTORS AT THE PARIS EXHIBITION.

M. de Fontainemoreau writes as follows:—

In accordance with the intention of the French Government, as intimated by M. de Forcade, Minister of Agriculture, Commerce, and Public Works in France, in his letter to my Paris correspondent, of which a translation was recently inserted in the *Journal* (p. 251), a bill was passed into law, on the 27th March, granting a "Certificat Descriptif," or provisional protection to exhibitors, non-patented in France, upon complying with the requirements enacted by such law, of which I beg to submit a translation for the information of your readers:—

Law of the 27th March, 1867, Protecting until the 1st April, 1868, Industrial Inventions and Manufacturing Designs admitted to the Universal Exhibition of 1867.

CLAUSE 1.—Any French or foreign subject being the author of a discovery or invention susceptible of being patented under the law of the 5th July, 1844, or of a manufacturing design, which may be registered pursuant to the law of the 18th March, 1806, or his representatives may, if admitted to the Universal Exhibition, obtain from the Imperial Commission of the Exhibition a certificate, descriptive of the article deposited. The application for his certificate must be made within one month, at latest, from the opening of the Exhibition.

CLAUSE 2.—This certificate secures to the person who obtains it the same rights as those conferred by a

Patent of Invention, dating from the day of admission by the French or foreign authority appointed to that department, until the 1st April, 1868, even should that admission be anterior to the promulgation of the present law, and without prejudice to the patent which the exhibitor may take, or of the registration he may effect before the expiration of that term.

CLAUSE 3.—The application for the certificate must be accompanied by a correct description of the article to be protected, and, if required, by a plan or drawing. These applications, together with the decisions taken by the Imperial Commission, shall be entered in a special register, which shall be ultimately lodged at the Ministry of Agriculture, Commerce, and Public Works. The issue of this certificate shall be gratuitous.

NEW FORM OF PORTFOLIO STAND.

The handling of large portfolios and books is often a matter of some difficulty. A novel form of portfolio stand has been contrived by Mr. F. H. McLauchlan, and is manufactured by Messrs. D. J. McLauchlan and Son, of Castle-court, Berners-street. It is so arranged that when closed it occupies less space than the usual kind of portfolio stand, and in opening the legs expand, giving greater stability. As the weight of the portfolio is partly balanced, the motion is very easy, and it will remain at any angle, or may be extended flat, in which position it can be fixed and used as a table. In one form the flaps are made solid for this purpose, and in another they enclose the contents as in a box. Various modifications enable it to be used for special purposes—thus, when intended as a stand for a large ledger, or similar book, it is made to open with the top inclined conveniently for writing.

Fine Arts.

MEMORIAL TO THOMAS STOTHARD.—It is proposed that a bust be executed by Mr. Weekes of the late Thomas Stothard, and placed in the National Gallery, by the side of similar memorials to deceased British artists. It is said that ample materials exist for an authentic likeness in the pictures by Harlowe and Green, the bust by Baily, and the cast by Chantrey. Stothard's "graceful and classical designs," in illustration of standard authors, it has been thought by numerous admirers, entitle the artist to the memorial now proposed. Several subscriptions have been already received. Mr. William Smith, of 20, Upper Southwick-street, Cambridge-square, acts as hon. treasurer and secretary.

Colonies.

LOCAL EXHIBITION AT BRITISH GUIANA.—A local exhibition of colonial products was held here early in the year, under the auspices of the Royal Agricultural and Commercial Society. It was formally opened by his Excellency the Lieutenant-Governor, who was welcomed by the president of the Royal Agricultural and Commercial Society, the president elect, the mayor of Georgetown, and several of the directors. The president read an address to the following effect:—After thanking his excellency for having consented to preside, reference was made to the exhibitions held in January, 1856, and August, 1861, and it was stated that the present exhibition, like the former, was not merely of a local character, for the purpose of promoting among all classes of the community competition in the development of the industrial resources of the colony, but was subsidiary to the representation of British Guiana at the Paris Exhibition of 1867. In addition to the advantages of the undertaking in its industrial, commercial, and scientific points of view, the meeting, for a common purpose, for a

large number of persons representing those of the different classes who were anxious to promote the interests of the country, must foster kindly feelings, and a sense of the benefits to be mutually derived from co-operation. Brief mention may be made of some of the most interesting objects in the rooms. Samples of vacuum pan and muscovado sugars of various qualities,—some of the former too white and good to admit of its being exported—and of white and coloured rum and molasses were exhibited and admired. There were some excellent specimens of different kinds of cotton, and an important display of starches, fibres, oils, medicinal plants and other valuable objects. There were cases of rare and curious birds. The collection of insects by Dr. Whitlock was excellent and well-arranged, the estimated value being £100. There were some fine fruits, flowers, and vegetables exhibited, and many and various articles remarkable for beauty, rarity or curious workmanship. A collection by Mr. Firth, sub-agent of immigration, of works having reference to the colony, its affairs, natural history or products, excited much interest. There were no less than 194 volumes and about 240 pamphlets, some of them of great antiquity. An extra prize of 50 dols. was awarded to Mr. Firth. The exhibition was kept open for six days. On the first day the charge for admission was half-a-crown, but on the other days only a shilling, and a sum somewhat exceeding £100 was realised. There is a disposition to have another local exhibition at the close of the present year. The feeling is gaining ground that to have one annually instead of quinquennially would do much good. Great praise is due to Dr. Whitlock, the honorary secretary to the Committee of Correspondence, for the skill he displayed, and the interest which he took in everything connected with the exhibition.

Publications Issued.

THE LABORATORY; a Weekly Record of Scientific Research. (*Firth, Cannon-street.*)—The first number of this new magazine appeared on the 6th April. The editor says, "in putting forth this, the first number of *The Laboratory*, we are actuated by the conviction that the want this journal is intended to supply has hitherto been inadequately met. We believe that the large and important class which includes the cultivators and students of experimental science has not, up to the present moment, been presented with a journal fully reflecting that which is being accomplished in the public and private laboratories of the United Kingdom. When a train of subtle scientific thought and labour has culminated in a great result, the ordinary journals take note of the fact; but the minor and tentative labours that contribute to rear the great edifice are left unnoticed till the work is completed. It is our intention to record these early efforts—these original investigations—whilst they are being made. We shall not wait until the theory be perfected—until the history be completed; we shall give the elements that are being used in building up the theory—the materials that, as we write, are growing into the history. We submit that at the present juncture, when new theories and new systems of notation are absorbing so much attention, the appearance of a journal which shall, in the respects already mentioned, differ from its contemporaries and rivals, must be warmly welcomed by the class to which it addresses itself."

A TREATISE ON COAL AND COAL-MINING. By Warrington Smyth, F.R.S., Chief Inspector of the Mines of the Crown and of the Duchy of Cornwall. (*Virtue, Brothers.*)—Mr. Smyth explains all the operations of coal-mining, together with the lighting and ventilation of the pits, and the securing of them against accidents. The work contains information on the extent of the coalfields throughout the world, including even those of Australia, China, and India. The author maintains

that, if things continue as they are going on at England will soon cease to have any advantage some parts of the Continent in the price of Europe itself will be exhausted of its combustible fuels. He is of opinion that the present ratio of increase in the exportation of coals will not be sustained, and that much may be done at home to its wasteful use of them.

Notes.

GAS LIGHTING.—At the last monthly meeting Glasgow Architectural Society, Mr. W. Johnston, city, read a paper "On Gas Lighting," in which he stated that the people of London tolerate the most and ill-fitted gas appliances in their shops and houses—gas so foul and coarse, street lamps of such construction, as would not be tolerated in any town in Scotland. He argued, from calculations he laid before the meeting, and from the experience of Glasgow, that the London gas companies are able to sell canal coal gas at 6s. 5d. per 1,000 of a quality $2\frac{1}{2}$ times better in illuminating power than which they now supply at 4s. and 4s. 6d. In conclusion of his paper he gave the following consuming gas:—For coarse gas, use No. 3 burners at moderate pressure; for canal gas, No. 3 fish-tail burners; renew the burners frequently; the pressure at the meter when it gets too strong, substitute new lights in all buildings instead of putting them in one spot; bring the lights as near as convenient to the place to be lighted; use in fitting full-sized gas pipes; select lamps which afford the least obstructions to the light; and above all, avail of low-priced appliances for gas lighting. Dr. Frazer, in his lecture at the Royal Institution, on the 2nd of March, remarked on the bad quality of gas supplied to London. He thought the public were not fairly treated by the gas companies. Sixteen months ago he had examined the London gas, and now he thought it to be considerably worse than it then was. He had seen no improvements in this direction since that time. Undoubtedly there had, and any invention which increased the cost of manufacture was eagerly seized upon those relating to improving the quality of the gas were entirely ignored. To obtain the same amount of light in London as is obtained in Edinburgh it was necessary to burn twice as much gas, to put up with twice as much heat caused by its combustion, and to inhale twice as much sulphurous acid. No gas ought to be considered good enough for use which did not give a light equal to twenty standard candles when burning five cubic feet per hour.

Correspondence.

COTTAGE BUILDING.—SIR,—Are you aware that the meeting of the Society in May, 1850, the attention of the meeting was called to a model of a three-roomed labourer's cottage, erected by Mr. W. N. Clay, at Haverhill, in Essex, at a cost, it was stated, of £10 only? These were described as formed of clay lumps, dried in the sun, having an admixture of straw in their composition. The roof was thatched, and the floor of concrete. Various modes of building, not only for cottages, but for houses of large size, in Cornwall, Hampshire, and the west of England, were mentioned by some members at the meeting, as well as the "Pisé work" used in Italy for churches and large buildings.—I am, &c., AN OLD MEMBER.

CONCRETE WALLS.—SIR,—In the short communication which appeared in the last *Journal*, respecting the cost of concrete dwellings, the printer has made an error, and placed "12 × 12 × 7," instead of 12 × 12 × 12, which is a very serious difference. I shall feel gratified

ligned if you would cause it to be rectified. I wish to say a few words respecting Nicol's patent slabs, the principal advantages of which are—economy of construction and of space; the partitions in no case need be more than three inches thick, but the generality of them only 1½ inch thick. They also have the advantage of not absorbing water or damp, and of giving the easily washable surface declared to be so desirable for hospitals. This may be of a light and cheerful appearance, so that papering is required. The walling is, from its substance, highly non-conducting and warm, and the building can be inhabited without danger of fevers, &c., to which newly-built brick houses are liable if inhabited as soon as completed.—I am, &c., SAMUEL SHARP.

FLAX AND FLAX MACHINERY.—**SIR,**—I am glad to find, from the report of the meeting of the 27th inst., that attention is again directed towards the cultivation and management of flax in England. The quantity and quality of flax fibre received from India has not been so satisfactory as was at one time anticipated, and it is now generally thought an effort should be made to extend the production in the British Isles. At present the prices paid for good flax fibre are very high, and should be amply remunerative to the farmer, under ordinary circumstances. The cost of scutching (or cleaning) has remained almost the same for years back, and this item of expense is not now so heavy in proportion to the value of the fibre as it was when I published my book on flax some years ago.* After many experiments and trials the old scutch mill is still preferred in this country, combined, however, with improved fluted metal rollers, for breaking the flax previous to the scutching operation. The old mill is now perhaps cheap enough, and the chief objection to it appears to be the unhealthy nature of the occupation, arising from the immense quantity of fine dust inhaled by the workers. Something might, no doubt, be done to correct this defect, by improved ventilation, &c. I fear there is little chance of a machine being invented that will not require skilled labour; the scutching process requires great judgment, and that cannot be had with untrained hands. The breaking machine alluded to on Wednesday evening is something like an American invention, introduced a few years ago into this country, with very moderate success. The scutching mill of Messrs. Rowan, described in my book (page 73), was not very unlike that recommended by Mr. Young; but it has not been generally adopted, and the old mill still carries off the palm in Ulster. If Mr. Young succeeds in perfecting an improved breaker and scutcher, he will confer a lasting benefit on the flax-growing community, and I wish him every success, though I feel the difficulties before him are, to say the least, serious. In the discussion at the meeting it was remarked by a speaker that the flax seed should be grown for crushing into cake. Now, experience here is in favour of using the bolls for feeding, and uncrushed. In fact, the flax is pulled before the seed is ripe. The seed being thus not mature, would, I fear, hardly pay, under these circumstances, for the expense of crushing; indeed most Irish growers still think the seed of so little importance, that in the majority of cases, I believe, it is never taken off at all, and completely lost in the watering process; a proceeding often defended on the plea that the fibre is improved by this mode of treatment, and will bring a higher price; the water is supposed to be made softer, and thus to act better in the retting process, owing to the presence of the oily seed; while it is further argued that taking off the bolls (or ripling) always, more or less, injures the ends of the fibre. I believe there is some truth in the latter assertion, but still ordinary care will prevent such an occurrence. I have every reason to think that the former idea, as to the water, is quite erroneous. There is, however, no doubt that ragweeds spread on the top of the flax in the steeping-pond have a good

effect; and several farmers—who have lately tried the use of this common Irish weed in this way—have thanked me for the suggestion, and stated they observed a marked advantage. Another fact I may mention as worthy of notice is, that a large flax crop extracts from the soil very much the same ingredients as the turnip crop; consequently, if grown closely together in a rotation, these crops become exhaustive, and the produce limited. Between turnips and flax, in rotation, there should be four or five years, and between flax and flax again, six or seven. Unless this is attended to, and the details of cultivation carefully looked after, flax will likely disappoint the grower; but, with a moderate amount of intelligence and skill, a profit, varying from £3 to £20 per acre, can be realised.—I am, &c., WILLIAM CHARLEY, J.P.
Seymour Hill, near Belfast, April 3, 1867.

MEETINGS FOR THE ENSUING WEEK.

- Mon.**..... London Inst., 7. Prof. Westwood, "On Entomology." Society of Engineers, 14. Discussion on Mr. Henry Davey's paper, "On Pumping Engines for Town Water Supply." Medical, 8. Victoria Inst., 8.
- Tues** ... Civil Engineers, 8. Col. Sir Wm. Denison, "The Suez Canal." Statistical, 8. Dr. Guy, "On the Mortality of London Hospitals, and, incidentally, on the Deaths in the Prisons and other Public Institutions of the Metropolis." Pathological, 8. Anthropological, 8. R. Horticultural, 8.
- Wed** ... Geological, 8. 1. Mr. Robert Etheridge, "On the Physical Structure of North Devon, and on the Palaeontological Value of the Devonian Fossils." 2. Mr. W. Whitaker, "On Subaerial Denudation; and on the Cliffs and Escarpments of the Chalk and Tertiaries."
- Thurs** ... Linnean, 8. Dr. Cobbold, "On the Prevalence of Entozoa in the Dog; with remarks on their Relation to Public Health." Zoological, 4. Chemical, 8.
- Fri** Philological, 8.

Journal of the Society of Arts.

FRIDAY, APRIL 12, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock :—

APRIL 24.—"On the Construction of Iron Ships, and their Preservation by Zinc Sheathing." By S. J. MACKIE, sq., F.G.S.

CANTOR LECTURES.

Mr. HULLAH's course, "On Music and Musical Instruments," will be extended by two additional lectures, as follows :—

LECTURE VII.—MONDAY, APRIL 29.

MUSICAL INSTRUMENTS (*continued*).—The Bow—The Key-board—The Violin—The Organ—The Clavichord.

LECTURE VIII.—MONDAY, MAY 6.

MODERN INSTRUMENTS, CHAMBER AND ORCHESTRAL.—The Pianoforte—Combination of Instruments—The Orchestra.

The lectures commence at eight o'clock, and are open to members, each of whom has the privilege of introducing one friend.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object. The following gentlemen constitute the Committee :—

Rt. Hon. C. B. Adderley, M.P.
C. W. Aitken.
Edward Akroyd, M.P., *Vice-Pres.*
Sir W. G. Armstrong, C.B.
A. S. Ayrton, M.P.
S. A. Beaumont.
John Bell, *Mem. of Council.*
Professor Bentley, *Mem. of Council.*
Lord Berners, *Vice-Pres.*
Hon. and Rev. S. Beest.
D. Robertson Blaine, *Mem. of Council.*
W. H. Bodkin (Assistant-Judge), *Vice-Pres.*
Sir J. P. Boileau, Bart., *Vice-Pres.*
R. K. Bowley.
Antonio Brady.
Rt. Hon. H. A. Bruce, M.P.
Decimus Burton.
C. Buxton, M.P.
The Earl of Caithness, *Vice-Pres.*
Lord Eustace Cecil, M.P.

R. L. Chance.
Harry Chester, *Vice-Pres.*
The Masters of the City Companies.
Henry Cole, C.B., *Vice-Pres.*
Robt. Coningsby.
Rt. Hon. W. Cowper, M.P.
Sir Francis Crossley, Bart., M.P.
J. Bailey Denton, *Mem. of Council.*
Lord de l'Isle and Dudley, *Vice-Pres.*
The Duke of Devonshire.
Charles Dickens.
James Easton, *Mem. of Council.*
C. W. Eborall.
Lord Ebury.
Lord Elcho, M.P.
William Fairbairn, F.R.S.
Professor Fawcett, M.P.
Peter Graham, *Mem. of Council.*
The Earl Granville, K.G., F.R.S., *Vice-Pres.*

The Earl Grosvenor.
Mr. Hansard.
G. W. Hastings.
Wm. Hawes, F.G.S., *Vice-Pres.*
J. Pope Hennessy.
Sir Rowland Hill, K.C.B.
Chandos Wren Hoskyns, *Vice-Pres.*
T. Hughes, M.P.
Blanchard Jerrold.
Rev. C. Kingsley.
Hon. A. F. Kinnaid, M.P.
Lord Henry G. Lennox, M.P., *Vice-Pres.*
The Bishop of London.
The Sheriffs of London and Middlesex.
Rt. Hon. Robt. Lowe, M.P.
Lord Lyttelton, *Vice-Pres.*
Archbishop Manning.
Henry Maudslay, *Mem. of Council.*
Rev. F. D. Maurice.
The Lord Mayor.
J. Stuart Mill, M.P.
Rev. Dr. Miller.
The Bishop of Oxford.
J. Slaney Pakington, *Mem. of Council.*
Right Hon. Sir John S. Pakington, Bart., M.P., *Vice-Pres.*

Alderman Sir B. S. Phillips.
Sir Thomas Phillips, Q.C., F.G.S., *Vice-Pres.*, *Chairman of the Council.*
The Duke of Richmond.
Rev. W. Rogers.
The Marquis of Salisbury, K.G., *Vice-Pres.*
Titus Salt.
Sir Francis Sandford, *Vice-Pres.*
Colonel Scott, R.E., *Mem. of Council.*
The Earl of Shaftesbury.
Benjamin Shaw, *Mem. of Council.*
Sir J. P. Kay Shuttleworth, Bart., *Vice-Pres.*
S. Smiles.
Seymour Toulon, *Treasurer.*
Thomas Twining, *Vice-Pres.*
Alderman Waterlow, *Mem. of Council.*
E. W. Watkin, M.P.
G. Watts.
George F. Wilson, F.R.S., *Mem. of Council.*
Vice-Chancellor Sir Wm. Page Wood, F.R.S., *Vice-Pres.*

The Council, on the recommendation of the Committee, have passed the following minute :—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government to facilitate the visits of skilled artisans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan :—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation ; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society,

who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

The following report has been made by the Secretary:—

To the Council of the Society for the Encouragement of Arts, Manufactures, and Commerce.

GENTLEMEN,—In compliance with the directions of the Council, I proceeded to Paris for the purpose of ascertaining what arrangements were likely to be available with regard to the lodging and boarding of such artisans as might visit Paris under the auspices of the Society.

I soon found, from inquiries made in various quarters, that little information of any value, as to the probable cost of private lodgings generally, or as to what lodgings would probably be available, was likely to be obtained; indeed, any figures or statements under this head at that time were not likely to be of any use, or in any way to be a guide to the deliberations of the Committee.

The prices asked at that time were exceptionally high, but there was every reason to believe that a reaction would take place, and that, after the exhibition had been open a short time, these prices would diminish.

Mr. Cook, the well-known excursionist, I found was prepared to contract for the lodging and boarding of 50 artisans per week, supplying two substantial meat meals per diem, for 6s. per head per day. I subsequently placed myself in communication with M. Le Play, the General Commissioner of the Exhibition, who informed me that a Special Commission had been formed, under a ministerial decree, for effecting the very objects I was in search of, and he gave me a special letter of introduction to the Chairman of that Commission, Mons. Devinck, formerly President of the Tribunal of Commerce for the Department of the Seine, and I had two interviews with that gentleman. It appears that the object of this Commission is to raise, by subscription or otherwise, funds for facilitating the visits to the exhibition of foremen, workmen, or labourers connected with industrial and agricultural pursuits, and for enabling them to study the exhibition in all its aspects.

The Commission proposes to raise a fund (to which the Emperor and Empress have subscribed largely) in order to provide lodging and board at a cheap rate for artisans, to assist workpeople in their travelling to and from Paris, and to supply gratuitously medical aid in case of sickness. Mons. Devinck informed me that the Commission expected to have under their control five thousand beds. These are situated in different parts of Paris and the outskirts. They have had placed at their disposal large buildings and barracks, and some of a temporary character have been specially erected in the neighbourhood of the exhibition, which will be furnished suitably for the purpose, and beds will be arranged in the rooms, four and upwards in each room. In one of the buildings it is said that several hundred beds will be placed in one room.

Arrangements are made for breakfasts and dinners on a large scale and at a cheap rate, in a building erected for the purpose, with access to the Champ de Mars, where 1,000 persons can take refreshments at one time.

These arrangements, more especially those for aiding workmen gratuitously in their travelling expenses, were intended for French workmen, but at the same time all the organisation of the Commission is intended to be available for the workmen of other countries.

It is also intended that guides, speaking English and such other languages as may be necessary, shall be provided to conduct the men over such workshops as they may wish to visit. M. Devinck stated that on receiving

notice a sufficient time beforehand, the Commission would be prepared to provide lodging for such men as might be sent over and recommended to their consideration by the Society of Arts, at a payment of one franc per night per head. Their breakfasts—a substantial meal of meat—and dinners would be obtainable in the building I have before named, at one franc per head on each meal.—I am, &c.,

P. LE NEVE FOSTER, Secretary.

P.S.—Since writing the above, I have received the following tariff of prices at the restaurant referred to in my letter:—

GRAND RESTAURANT OMNIBUS, PARC DE L'EXPOSITION (AVENUE LAMOTTE-PIQUET).

Prix des objets de consommation.

	Ofr.	Kc.
Pain	0	15
Vin, le carafon	0	25
Bière, la chope	0	15
Bouillon	0	30
Potage	0	25
Bœuf	0	25
Légumes	0	15
Fromage	0	30
Café avec eau-de-vie	0	40
Roti avec légumes	0	40

On peut demander un seul des objets de consommation ci-dessus mentionnés.

Le consommateur, en apportant son pain, peut se procurer pour 0fr. 40c. l'ordinaire (bouillon et bœuf).

Members are invited to aid the Council in the undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

The Council have received offers of co-operation from a Committee for promoting cheap excursions to the Exhibition, formed under the auspices of the "Working Men's Club and Institute Union," and of which Mr. A. H. Laved M.P., is President, and Mr. Hodgson Pratt, Vice-President. A deputation from this Committee, consisting of Mr. Hodgson Pratt, Mr. W. Glacier, Mr. Paterson, and Mr. W. O. Pocklington, Secretary to the Committee, has had an interview with the Chairman of the Council and Mr. W. Hawes on the subject.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

The Sub-Committee on meat met on Wednesday, the 27th March. Present: Benjamin Shaw, Esq., in the chair. Messrs. Harry Chester, C. S. Read, M.P., J. Ware, and E. Wilson.

In reply to questions from the Chairman and the members of the committee,

Mr. A. SLATER, who had kindly attended at the request of the Committee said—*I am a butcher, carrying on a large business in London, and am well ac-*

maintained with the meat trade; not only a large number of animals are slaughtered in my establishment, but I may largely meat slaughtered in the country. Meat, in order to travel in good order, must have been killed some short time before it is packed. It must be what we call "set." The time required for this differs at different seasons of the year; it will soon get set in cold weather, but in warm weather should certainly give it one night; we kill as late in the day as possible in summer time, in order to get rid of the animal heat and moisture during the night.

MR. CHESTER—Do you use any artificial means for trying it?

MR. SLATER—No; we merely let it have air. If we want to use the meat quickly in summer time we should cut it up as soon as we could after it was killed; sometimes it happens that on a Saturday night poor people want their piece of meat for Sunday, and we kill a number of sheep in sultry weather always on Saturday night for poor people, because they have no convenience for keeping it. I have several places of business, one at Kensington, one in Jermyn-street, one in Piccadilly, but I kill only at Kensington.

MR. CHESTER—Did you find there was any considerable difficulty in carrying on your business since the regulations which have been imposed by the Government on the movement of cattle consequent on the cattle plague?

MR. SLATER—I did at first. The difficulty was, I could not get the dead meat up regularly. For instance, I had bought a lot of meat from one, and sent for it to come to town on Tuesday; another, to let it come on Wednesday, and another on Thursday; up came all sorts of excuses; they were very sorry they could not get it butchered; for two or three days I was without meat, the third day I got the whole lot up at once. I do not, however, say, kill everything in London; but I do not think a butcher's business can in summer time be carried on with any advantage to the public, unless we have our own slaughter-houses. The dead meat which I buy comes from all parts. Meat from Scotland comes in better condition than from any other part. We cannot, however, always rely on its coming in good condition. I do not know how long it is on the journey from Scotland, because in some instances it comes by the ordinary traffic, whilst in some instances they have special trains for it. I believe they have special arrangements on railways for the carriage of dead meat, but I think a salesman would give you better information about that. I believe, if it is not conveyed by a certain time from some places, that the railways are subject to a penalty, but that is only from some places; there are no special vans for meat; it is tumbled in any way.

MR. CHESTER—Do you think the meat is injured owing to the manner of loading it?

MR. SLATER—Certainly; of course, in hot weather, if you put a lot of meat together it injures it, for where it rubs together you find a lather like soap, but when it is packed in canvas you do not notice that. If I killed at a very distant place instead of Kensington, I should like to have a carriage built on purpose, so that when I had killed the meat I could put it in that carriage, and hang it as close as I could pack it. I would send it to the railway at once, so that there should be no handling of the meat. I should not care to pack it in canvas if I had a carriage built on purpose, as I would hang it up warm as soon as I killed it, so as not to have it touched, at least until I got it to the shop. I would quarter the carcasses of beef, but not divide them further; I should keep them in sides as long as I could; on a railway of course I could not do this—the carriage would not be high enough, and I should have to cut them—to quarter them—but I would not cut them smaller than quarters. I think that is the best way of sending meat. There is considerable loss to a butcher from change of weather, but we lose more in winter than in summer; the wind wastes it a good

deal—more juices dry out of the meat; there is an invisible waste always going on in meat, particularly in wind and frost. The object of admitting air after the meat is killed is for coolness, not for any other object. The absence of air is of no importance, provided coolness is obtained; the air is used simply as a means of producing cold, but damp must be avoided. The waste I spoke of just now arises from hanging in the air; any contrivance which would keep the meat sweet, without subjecting it to a current of air would be a great gain in my business, supposing I had room for the purpose.

MR. CHESTER—Professor Gamgee believes that meat killed according to his plan, will keep six weeks, even without being afterwards immersed in any preservative gas.

MR. SLATER—I do not know what is lost in weight by evaporation; I have never tried; mutton, however, wastes more than beef. There is no loss to the buyer at all, because it is only the water that is driven off; there is a loss to the butcher. This loss, in winter, is simply the loss of weight, and the loss in summer is the absolute destruction of meat from being putrid.

MR. WILSON—What becomes of the offal—the hearts, and things of that kind? Do you find a sale for them?

MR. SLATER—Yes; they sell very readily. In the winter time they sell very well; in summer time, of course, we can never be over-nice about price; if anybody offers a fair and reasonable price they are sold.

MR. WILSON—On an average, through the year, how much per pound?

MR. SLATER—We do not sell them by the pound, but by the lump. I will, however, let you know; I will go carefully through all, and weigh them. I sell them all at Kensington. I encourage people there to come for them; at the other shops, not killing there, the people have never had that sort of thing exposed, or rarely, if ever; and therefore they are not asked for.

MR. MICHAEL—Do you make any arrangement for getting rid of the meat when it gets unsaleable as first quality, or is it entire waste?

MR. SLATER—We watch it carefully, that is all.

MR. MICHAEL—What do you do supposing it is just beginning to turn, so that you cannot sell it to first-class customers; is there any plan of selling that to another class of customers?

MR. SLATER—We do not expose it for sale at all. We boil it to get the fat and we save the bones. The meat is absolute waste. That is generally the plan adopted. It is not sold as a damaged article to make soup of, or for any other purpose. If in the market any meat is putrid and bad, the inspectors condemn it, and they take it away and boil it, because the fat is just as good for the tallow-chandlers, whether the meat is putrid or sweet, and the meat is buried, I believe. Supposing I have a very large stock, and I find, on looking over that stock at night, that some of it is beginning to lose its quality, there is no means of disposing of it at all. There is no class of customers on the look-out for that. There may be a low class of butchers who would buy it, but that is very exceptional. There is no organised system of getting this from the first-class butchers. I do not know of any plan adopted of selling the meat at a lower price, when it has lost its first quality, to a lower class of customers. It is either sweet and wholesome, or bad. I can make no distinction. There is no intermediate state. In fact, it is a butcher's business to keep it just long enough, and not too long. It cannot be used by cutting off the external surface. It generally goes inside first. It goes first at the kernels and veins; in summer time we open all the kernels, and take them out, or let the air into them. If the kernels were removed, sometimes a leg of mutton would be good which otherwise would not.

MR. WILSON—In the case of the large quantity of dead meat that comes up from the country, does the offal of that dead meat come up, or is it sold where the slaughter takes place?

Mr. SLATER—Some comes up, and some is sold at the place of slaughtering. Nothing like half comes up; it is only from some districts, where they have no sale for it, that it comes.

Mr. CHESTER—Is there any difficulty, in consequence of the butcher's joints being cut in a different way?

Mr. SLATER—Every county and town has a different way of cutting up meat, and you may as well try to change a man's name as to alter it. I think the Scotchmen have at last been persuaded to take out the kidney fat. I asked a salesman "why don't you write to these people to take the kidneys out of these sheep, for if they would take them out the meat would keep?" and he said—"You have only to ask a man to alter his plan to lose his business." But some of them gave in to the sensible plan of taking out the kidney, or even removing it altogether, and the meat is good.

Mr. SHAW—Have you heard anything of the plan of bringing meat from the south of Ireland, fresh meat, not salt, by means of fast steamers?

Mr. SLATER—I have heard that Mr. Wood, of the Great Western Railway, was very sanguine about it, but I do not know whether it will be remunerative.

Mr. CHESTER—Does much bad meat come from Holland?

Mr. SLATER—Not much. It depends altogether on the passage and the way in which it is brought. If it is brought from Holland not properly packed, and there is a bad passage, it ships a lot of water, and nothing is worse than sea-water for meat. Some comes from Scotland by rail, and some by boat, and that which comes by boat is not so easily disposed of.

Mr. SHAW—You always know where meat comes from?

Mr. SLATER—Yes; I know exactly, by the appearance, what country it comes from, and all about it, by the shape of the meat. Some meat came from Holland last year in very good order indeed, some came in very bad order; it depends very much how it is managed. We have had very good meat from Holland this year.

Mr. CHESTER—Do you do much in the way of salting meat?

Mr. SLATER—Not with any idea of salting it for preservation. I merely salt for my own trade.

Mr. CHESTER—What is the loss of weight in meat that has been salted?

Mr. SLATER—I never tried. It would depend on whether it was left to drain.

Mr. MICHAEL—Under any circumstances the salt meat must lose a great quantity of juice, which is turned into brine. Do you adopt the dry principle?

Mr. SLATER—There is dry salting; some people prefer it. If you dry salt meat it will make a gravy just the same. I never tried the difference between the wet and dry salting. I will try it. I will take two pieces, and dry salt one and wet salt the other, and give them both the same time.

Mr. CHESTER—Is there any difference in the amount of difficulty in managing the meat which you kill yourself and that killed in the country?

Mr. SLATER—Generally, the country butchers are very clean dressers. There is not much difficulty in that way.

Mr. CHESTER—Do you know how long it has been killed; and when you get it is there any certificate, or any thing of that sort?

Mr. SLATER—None at all; you can tell by the appearance for a day or two, but after that you cannot. Scotch meat is better, on account of being killed in a cooler climate; and besides this, the cattle are not killed after a long railway journey, and they are in a quiet state. A great deal depends upon what state the animal is in when he is killed whether the meat will keep.

Mr. READ—What do you generally find is the fact as to meat killed in the country in a quiet way, and the cattle you have here from the London market after they have gone a long journey?

Mr. SLATER—I keep them at home a short time before I kill them; I do not kill them what we call "off the drift;" if killed as soon as they arrived the meat would not keep. I keep them until the next day, and that is sufficient. They soon get quiet and settle down.

Mr. SHAW—I understand you to say that meat cannot be brought up in a good condition in the summer, on account of the heat. If that mode of transit could be improved, that objection would be met?

Mr. SLATER—Certainly.

Mr. CHESTER—If there were special vans constructed, admitting air but not dust, and kept at a low temperature, either by a small quantity of ice or by means of evaporation, might not meat come in very good condition a long way?

Mr. SLATER—I do not think ice good for meat. I have an ice-house myself; and I used it for two or three seasons, but last season I dispensed with it, because the action of the air alters the appearance of the meat directly you bring it out. You have a joint of meat and you bring it out to all appearance beautiful and firm, and clean, as when you first put it in; it remains in the shop say for an hour, and you then see a sweat on it, and it takes up every particle of dust and everything which touches it, and when it gets to the customer's house it is objected to.

Mr. CHESTER—What temperature is your ice-house?

Mr. SLATER—About 40 or 45 degrees. If by any artificial means in the vans you could create a cool air, it would no doubt be beneficial.

Mr. CHESTER—Does your principal supply of live meat come consigned to you, or do you go into the market and buy it?

Mr. SLATER—I get a great deal consigned to me, and I go into the market and buy what I want besides. It comes from different gentlemen, not graziers in business, but gentlemen who have so many bullocks and so many sheep. They write and say they have so many ready, and they are going to send them up.

Mr. SHAW—It was said, after the passing of the free trade measures of Sir Robert Peel, that they had not produced any effect on the price of meat, for this reason, that foreign meat did not compete with the best English meat, and was not used for the tables of persons who wanted the best articles, but that a new class of meat consumers were brought into existence. Is that your opinion?

Mr. SLATER—It is. I do not think foreign meat will ever compete with first-class English meat, but it will set so much more first-class meat at liberty, so to speak, for the higher tables. In time we may get better meat from abroad, when herds are improved, and they are better fattened. There is nothing in the transit which necessarily makes the meat inferior if properly managed. I certainly do not like beasts coming from abroad, from the mere fact of their having had a sea voyage. I do not think it does them any good; I think it affects a bullock or a sheep the same as it does a human being. The dead meat comes better. I should rather buy it dead than alive.

Mr. WILSON—Do you think, from your experience, that the meat can be sufficiently ventilated during a long railway transit without the accumulation of dust to any disagreeable extent?

Mr. SLATER—I do not think it can, unless a van were so constructed as to completely exclude dust, and still let in air. Canvas sides would stop a great deal of it.

Mr. READ—When you said you did not like foreign cattle because they came by steamboat, of course that would apply to those which came by sea from Scotland and Ireland?

Mr. SLATER—They are as bad as foreigners.

Mr. READ—You think Irish cattle had better be killed there if possible, and sent dead?

Mr. SLATER—Yes; if they would come in a good state. The objection to the dead meat trade from Ireland would apply more in the summer than in the winter unless you

had a quick transit for it. There is no reason why meat coming from Ireland should not be as good as that coming from Scotland.

MR. WILSON—Is there any tendency to the establishment of large slaughtering-houses, out of London, but short of a long railway transit? It seems to me that, with the difficulty of conveying dead meat, and the difficulty of slaughtering in London, it would follow that somebody would find it worth while to establish large slaughtering places at short distances out of London, and without involving a long railway journey. Is there any tendency in that direction?

MR. SLATER—I think if you were to establish large slaughter-houses of that sort, and get rid of private slaughter-houses altogether, you would get two distinct trades. A butcher as he is now would not be a butcher then, he would be a purveyor of meat. I for one, if you did away with my private slaughter-house, would not kill at all. I would stand the chance of buying it dead. There is a great objection to have abattoirs by butchers. They like to have their private slaughter-houses; they object to slaughter-houses not under their own control. I would never buy another live animal, if I could not kill it at home. Of course an animal brought out of the field, from his own natural pasture, and killed quietly in a man's own slaughter-house, would be in a better state than if he were conveyed to London. Even when he is sent home to my place and kept a few days he does not recover the same degree of quality—he has lost a certain portion.

MR. READ—But with regard to the question—if a bullock had to come a certain distance by rail to a certain great centre, it would be almost as bad as killing in London would it not?

MR. SLATER—Yes.

Proceedings of Institutions.

EXAMINATIONS, 1867.—LIST OF LOCAL BOARDS.

ABERDEEN.—**MR. W. BRENNER**, *Chairman*; **Rev. John Longmuir**, LL.D.; **J. Cruickshank**, LL.D., late Prof. of Mathematics; **J. S. Brazier**, Prof. of Chemistry; **R. Beveridge**, M.D.; **Messrs. W. Rattray**, **D. Mavor**, and **P. Cleland**. The above constitute the *working* Local Board. The following are also *ex-officio* members:—The Lord Provost of Aberdeen, the Senior Baillie of Aberdeen, the Dean of Guild, Aberdeen, John Manson, James W. Barclay, John R. McKenzie, George Falconer, Alexander Yale, Baillie M. Hardy, Messrs. J. Duguid Milne, J. Miller, James Matthews, T. Melville, W. Fraser, J. Berry, A. D. Milne, J. Gray, and R. Lays; **Mr. J. Sinclair**, Mechanics' Institution, Aberdeen, *Secretary*.

ACOMS (YORK).—**Rev. Isaac Spencer**, M.A., Vicar; **Messrs. P. Hayne**, **G. Cullen**, and **T. Copley**, *Secretary*.

ALDESHOT AND FARNHAM.—**Captain E. E. Mangles**, *Chairman*; **Dr. Barker**, Messrs. **W. H. Bayley**, **J. Belling**, B.A., — **Bevan**, **Rev. R. Campbell**, **W. W. Chettle**, **R. O. Clarke**, **Geo. Dewdney**, B.A.; **Sir C. W. Dilke**, Bart., M.P.; Messrs. **F. Eggar**, **Rev. Geo. Fox**, **Rev. H. R. Julius**, M.A., — **Mason**, **Rev. D. Malden**, **Thomas W. Mayer**, R.E.; **Rev. S. C. Morgan**, M.A.; **Capt. G. Newcome**, J.P.; **Lieut-Col. Newdigate**, the Staff, Messrs. **B. Nichols**, — **Ollie**, **H. Poppleton**, L.C.P., **E. Powell**, **S. Redgrave**, **George Slater-Booth**, Esq., M.P.; **Dr. J. Shoolbraid**, M.D.; Messrs. **Sloman**, **C. Stroud**, the Ven. Archdeacon Utterson, **Rev. J. Webster**, Messrs. **T. White**, **T. Wonnacott**, **W. Hollett**, *Treasurer*, and **Barrow Bule**, Classical and Mathematical School, Aldershot, *Secretary*.

ALTON.—**Mr. William Curtis**, *Chairman*; Messrs. **W. Curtis**, jun., **Samuel Bickerton**, **Edwin Williams**, and **John Bryant**, Post-office, Alton, *Secretary*.

ASHFORD.—**Revs. J. P. Alcock**, **R. H. Wright**, M.A. and **W. Anderson**; Messrs. **J. J. Cudworth**, **R. C. Mansell**, **T. H. Vie**, **J. Keener**, **R. Raboon**, **F. Garaway**, and **Thomas Nesbit**, 11, Dover-place, Ashford, *Secretary*.

BANBRIDGE (IRELAND).—**Mr. W. Waugh**, J.P., *Chairman*; **Mr. R. McClelland**, *Vice-Chairman*; Messrs. **J. W. McMaster**, **J. P. A. Love**, **J. Hawthorn**, M.D., **J. Smyth**, jun., C.E., **G. G. Tyrrell**, **W. Walker**, **G. F. Long**, **H. Finlay**, **J. Noble**, **H. Glass**, **T. Connor**, **R. Davidson**, and **Hugh McMullan**, jun., Dromore-street, *Secretary*.

BANBURY.—**Rev. H. Back**, *Chairman*; Messrs. **T. W. Barrows**, **T. Bealey**, F.C.S., **R. H. Brooke**, **W. Johnson**, F.R.A.S., **D. Pidgion**, A. B. Rye, F.R.C.S., **J. Stockton**, **Rev. G. St. Clair**, F.G.S., A. Wilson, M.A., **Mr. J. H. Beale**, Mechanics' Institute, Banbury, *Secretary*.

BEESTON (LEICESTER).—Messrs. **Horatio Goldthorpe**, **David Roberts**, **Edward Thornton**, **Tom C. Sumner**, **Samuel Milner**, **Benjamin Slater**, and **William Standeven**, *Secretary*.

BELFAST LITERARY INSTITUTE.—**Mr. Joseph J. Murphy**, *Chairman*; **Revs. Isaac Newton**, **John Scott Porter**; Messrs. **Robert Patterson**, **Thomas McClintock**, **Charles Hennie**, **John Ireland**, **Thomas J. McConkey**, **Wm. T. Matier**, **Robert Jamieson**, **Thomas Morrison**, **Francis A. Maitland**; **Rev. W. C. McCullagh**, *Secretary*.

BELFAST SCIENCE SCHOOL.—**John Lytle**, Esq., J.P., *Chairman*; **David Taylor**, Esq. (Mayor of Belfast); **Wm. Mullan**, Esq., J.P. (Ex-mayor); **Dr. Andrews**, Vice-President, Queen's College, Belfast; **Dr. Hodges**, Professor, Queen's College, Belfast; **Rev. J. Macnoughtan**, M.A.; **T. M. Birnie**, Esq., J.P.; **R. Nesbitt**, Esq., Inspector of Schools; **R. C. Brown**, Esq., A.M.; **C. Aitchison**, Esq.; **S. D. S. Cunningham**, Esq.; **Robert Patterson**, Esq., F.R.S.; **Thomas Lowry**, Esq.; **James Alexander**, Esq., J.P.; **James Patten**, Esq., LL.D., late Head Inspector of Schools; **Rev. Thomas Toye**; **Archibald Kent**, Esq.; **Wm. Warwick**, Esq., M.D., M.R.C.S.E.; **Wm. Gibson**, Esq.; **John Molloy**, Esq., Inspector of Schools; **H. Hanna**, Esq., M.D., M.R.C.S.E.; **Henry Murphy**, Esq.; **G. Gerald Bingham**, Esq.; **D. Pasley**, Esq.; and **James McNeill**, *Secretary*.

BESBROOK (NEWRY).—Messrs. **James N. Richardson**, Jun., *Chairman*; **John B. Doyle**, F.R.G.S., **J. Joseph Lightburne**, M.D.; **Wm. J. Worsfor**, Besbrook, Newry, *Secretary*.

BIRMINGHAM AND MIDLAND.—**Matthew Davenport Hill**, Esq., Q.C., *Chairman*; Messrs. **Thomas Martineau**, the **Rev. G. D. Boyle**, M.A., **Thomas Avery**, the **Rev. Charles Evans**, M.A., and the **Rev. T. E. Espin**, B.D., the Right Hon. **Lord Leigh**, **George Dixon**, Esq., Mayor of Birmingham; **Mr. Alderman Ryland**, **Mr. Alderman Sturge**, and **Mr. Alderman Wiggin**, Councillor **Stephen Barker**, Messrs. **W. C. Aitken**, **J. B. Busee**, **J. H. Chamberlain**, **Sebastian Evans**, M.A., **J. B. Gausby**, **Alfred Hill**, **Trehawke Kekewich**, **Wm. Kenrick**, **Wm. Mathews**, jun., M.A., **C. T. Parsons**, **Samuel Timmins**, and **Edwin Smith**, Birmingham and Midland Institute, Birmingham, *Secretary*.

BISHOPS' STORTFORD.—**Rev. T. L. Bayliff**, M.A., *Chairman*; **Mr. J. Bell**, M.A.; **Rev. W. J. Copeland**, B.D.; **Revs. G. Goodman**, **J. Menet**, M.A.; Messrs. **G. A. Starling**, M.D., L.R.C.P., and **F. W. Nash**, B.A., Bitchanger, Bishops' Stortford, *Secretary*.

BLANDFORD.—Messrs. **S. Abbott**, *Chairman*, **E. Fisher**, **W. E. Groves**, and **J. B. Green**, *Secretary*.

BODMIN.—**Henry Mudge**, Esq., J.P., Messrs. **John Crang**, **Joel D. Williams**, and **Josias Philipps**, Little Berry cottage, Bodmin, *Secretary*.

BRADFORD.—**Rev. D. Fraser**, LL.D., *Chairman*; **Rev. J. Burnet**, LL.D. (vicar); Messrs. **J. Barker**, **J. G. Best**, **J. H. Bridges**, M.D.; **Rev. J. R. Campbell**, D.D.; Messrs. **J. A. Clapham**, **T. Clark**, **L. Clough**, **D. J. Crebbin**, **W. H. Evans**, M.D., **J. Hanson**, **C. E. Hey**, **J. Hey**, **Alderman Law**, **C. Lund**, **J. T. Newbould**; **Rev. W. C. Shearer**, M.A.; Messrs. **A. Smith**, **S. Smith**, **J. B. T.**

B. Wainwright, A. Walker; Rev. T. T. Waterman, B.A.; Mr. Willie, Ph.D.; Mr. J. Holbrey, Mechanics' Institute, *Secretary*.

BRIGHTON.—The Mayor of Brighton, James White, M.P., W. Furner, David Black, Howard Elphinstone, M.A., Henry Moor, and Arthur Bigge, M.A., Esqrs.; Rev. Canon Sainsion; Revs. J. Griffiths, M.A., J. B. Mozley, B.D., James Walter Cary, D.D., W. Kelly, M.A., John Allen, A.B., J. H. Cross, M.A.; Drs. Louis Loewe and C. White; Messrs. Albert Creak, M.A., William Alger, J.P., W. R. Barrymore, Bastick, L. Bridgen, J. C. Burrows, J.P., Philip Capon, Charles Carpenter, J.P., Charles Chalk, Alfred Cox, Samuel Evershed, W. H. Harper, H. E. Harris, J. H. Hutton, W. T. Loveday, E. J. Marshall, H. Martin, William Olding, Thomas Page, George De Paris, John Peto, F.R.A.S., Montague Penley, W. W. Pyne, Pridaux S. Rickards, W. D. Savage, J. H. Scott, William Sleight, H. Treacher, Wm. J. Williams; Messrs. Scott and Sleight, *Auditors*; Mr. T. W. Wonfor, *Treasurer*; Mr. Barclay Phillips, 75, Lansdowne-place, Brighton, *Honorary Secretary*.

BRISTOL.—Rev. Canon Girdlestone, M.A., *Chairman*; Mr. G. C. Ashmead; Revs. T. Bowman, M.A., C. Brittain, M.A.; Mr. F. N. Budd, M.A.; Rev. J. Burder, M.A.; Messrs. I. A. Cooke, J. D. Corfe; Earl of Ducie; Mr. J. F. R. Daniel; Mr. P. H. Edlin; Very Rev. G. Elliott, D.D., Dean of Bristol; Sir A. H. Elton, Bart.; Mr. J. S. Fry, Rev. Professor Gotch, LL.D.; Mr. F. W. Griffin, Ph.D.; Rev. N. Haycroft, M.A.; Messrs. F. Hazeldine, B.A., Mr. Commissioner Hill, C. T. Hudson, M.A., W. H. G. Langton, H. Brittan, Revs. Precentor Poole, M.A., J. Robertson, A.M., D. Thomas, B.A., Messrs. F. F. Tuckett, R. H. Webb, J. C. Wallis, W. C. Seaton, Rev. J. R. Wreford, D.D., Mr. M. Whitwill, and Robert C. W. Ross, *Secretary*.

BROMLEY (KENT) LIT. INST.—Rev. H. C. Adams, M.A., *Chairman*; Rev. A. G. Hellicar, M.A. (Incumbent of Bromley); Messrs. S. P. Aeton, J. W. Ilott, M.R.C.S., &c., and W. W. Baxter, *Secretary*.

BURY ST. EDMUND'S.—The Hon. and Venerable Lord A. Hervey, *President*; Sir C. J. F. Bunbury, Bart.; Mr. J. W. Goodwin, M.D.; Rev. A. H. Watislaw, M.A.; Messrs. R. F. Aldridge, R. Craske; and Mr. J. Jackson, Head Master of the Guildhall School, *Secretary*.

CALVERLEY (LEEDS).—Messrs. Joseph Gott, J. Grainger, and Alfred Walton, *Secretary*.

CANTERBURY.—The Very Rev. the Dean of Canterbury, D.D., *Chairman*; Mr. J. S. Linford; Revs. J. Mitchinson, D.C.L., A. P. Moor, M.A., M.R.A.S., F.R.G.S., and E. R. Orger, M.A., Mons. L. I. Razé, Rev. J. C. Robertson, M.A., and Mr. W. D. Furley, St. George's-place, Canterbury, *Secretary*.

CARLISLE MECHANICS' INSTITUTE.—R. Ferguson, Esq., *Chairman*; A. Davidson, Esq., Messrs. J. Sewell, W. H. Nutter, T. H. Hannah, W. Constable, J. T. Cockburn, and Mrs. Jane Williamson, Mechanics' Institute, Fishers-street, Carlisle, *Secretary*.

CARLISLE WORKING MEN'S READING ROOM.—Mr. Edward Harris, *President*; Messrs. Matthew Burrow, Robert Sanderson, Thomas Forsyth, and John Short, Lord-street School, *Secretary*.

CHATHAM, ROCHESTER, STROOD, AND BROMPTON.—C. Dickens, Esq., *Chairman*; Drs. W. Burns, LL.D., J. D. Burns, M.D., Messrs. E. A. Bernays, H. G. Adams Daddon, Rev. A. R. Webster, M.A., Mr. S. Heckford, Mr. J. Norman, and Mr. F. Butler, 112, High-street, Chatham, *Secretary*.

CHELMSFORD.—Rev. C. W. Arnold, M.A.; Messrs. D. Wheeler, J. A. Copland, T. Moss, Hunt, J. Church, S. H. Sharman, G. Seaton, C. Pertwee, W. Cutts, and Jesse Garrod, *Secretary*.

CHRISTCHURCH.—Mr. J. Drutt, *Chairman*; Rev. Z. Nash, M.A., Rev. J. Fletcher, Messrs. F. Moser, J. Clark, R.A., H. Stokes, Mr. H. Jenkins, J. E. Holloway, and Mr. W. Judd, F.C.S., High-st., Christchurch, *Secretary*.

DEPTFORD.—Rev. C. F. S. Money, M.A., *Chairman*; Revs. G. Lacey, M.A., A. J. Myers, M.A., Dani Campbell, B.A.; Messrs. H. E. Montgomerie, F.R.S., J. J. Bennett, F.R.S., F. Ball, R. West, J. Watkins, T. Earland, 2, Wellington-grove, Greenwich-road, S.E. *Secretary*.

DERBY.—Mr. W. T. Cox, M.P., *Chairman*; the Mayor of Derby, Rev. W. F. Wilkinson, Rev. E. Geare, Dr. Goode, Messrs. J. Davis, F. M. Haywood, A. J. Hely, J. Hudson, R. Geare, C. Greaves, N. Greaves, J. J. Hunt, C. Pratt, and C. Holmes; H. M. Holmes, London-road, Derby, *Secretary*.

DEVONPORT.—The Right Worshipful the Mayor, T. Peek, Esq.; the President of the Institute, R. C. S. Esq.; the Vice-Presidents, R. Oram, R.N., A. Nran, F. Row, M.D.; and R. C. Rogers, Esqrs.; the Rev. H. Everett, M.A., J. Metcalfe, M.A., and J. Stoddard, Messrs. F. Burt, C. Croydon, P. F. Delarue, L. Dore, W. Hannaford, U. H. King, T. W. Miller, T. Mearns, Radford, R. H. Rae, C. Row, J. W. W. Rowe, J. E. Shapton, P. W. Swain, R. Townshend, and T. W. W. Mogg, and S. Chapple, Mechanics' Institute, *Secretaries*.

EAST LANCASHIRE UNION OF MECHANICS' INSTITUTES (BURNLEY.—CENTRAL BOARD).—Sir J. P. Kay-Shuttleworth, Bart., *Chairman*; Messrs. J. Binns, J. S. Burt, T. Newbigging, J. Rawstron, B. W. Briggs, J. W. R. Rawlinson, R. Slater, J. Graham, J. C. Bussell, M.D., T. Dean, M.D., J. Green, E. Foden, J. Seaton, Turner, E. Lord, H. Houlding, T. Lister, H. P. Williams, R. Nelson, J. Rawlinson, W. F. E. Howarth, R. Howarth, J. Pollard, J. H. Scott, J. Waddington, J. B. Whitehead, R. Whittaker, T. T. Wilson, F.R.A.S., U. J. Kay-Shuttleworth, W. B. J.P., *Treasurer*; J. Sutherland, Post-office, Burnley *Secretary*; T. W. Shore, *Organising Master and Assn. Sec.*

BAOP. (See Lancashire and Cheshire Union.)

HASLINGDEN.—Mr. R. M. Townsend, *Chairman*; Messrs. A. Howarth, J. Furneal, Abram Hindle, G. Dean, J. Isherwood, J. Wade, L. Barlow, J. Eastwood; Dr. J. Binns, *Secretary*.

RAWTENSTALL. (See Lancashire and Cheshire Union.)

PADIHAM CHURCH OF ENGLAND EVENING SCHOOL.—Rev. J. Hamilton Fox, *Chairman*; Rev. G. A. Messrs. R. Thompson, W. Waddington, T. H. Sheburn; Rev. P. Warburton, *Secretary*.

LOMESHAYE EVENING SCHOOL.—Mr. W. E. Ward, *Chairman*; W. F. E. Crody, J.P., E. E. Crody, Esq., Messrs. G. Austerfield, J. Waddington, J. C. H. Nutter, J. Heap, H. Edmondson; Leonard Clement, *Secretary*.

ECOLSHILL (LEEDS).—Messrs. Samuel Smith, W. Holmes Hutton, and John Thomas Baxter, *Secretary*.

EDINBURGH WATT INSTITUTE AND SCHOOL OF ARTS.—Rev. W. H. Gray, M.A., *Chairman*; Messrs. Robert Cox, John Crombie, John Robertson, Sibbald, M.D., Thos. Murray, LL.D., W. Smith, J. Russell, R. M. Ferguson, Ph.D., George Rowe, B.A., W. T. McCulloch, and F. W. Bedford, D.C.L., Heriot's Hospital, Edinburgh, *Secretary*.

FABLEY (NEAR LEEDS).—Messrs. John Marshall, Time-theus Foster, James Turner, Daniel Ainsworth, 12, Arthur Kirk, *Secretary*.

FAVERHAM.—S. G. Johnson, Esq., *Chairman*; Rev. J. R. Cooke, M.A., Messrs. F. F. Giraud, G. Robinson, J. M. Cowper, J. A. Anderson, Paul, Batterbee, C. Smith, and Frederick W. Monk, 9, Albion-terrace, Faversham, *Secretary*.

GARFORTH (LEEDS).—Messrs. H. J. Morton, Geo. Morley, J. Pick, Schofield, Quarumby, and Arthur Washhead, *Secretary*.

GILFORD (IRELAND).—John W. M'Master, Esq., J.P., James Dickson, Esq., Ben. Dickson, Esq., J.P.; Revs. W. Gordon, Jonathan Harding, James Orr, Thomas Frazer, Esq.; and Dr. Henry M'Bride, Gilford, co. Down, *Secretary*.

GLASGOW ATHENÆUM.—The Very Rev. Principal Barclay, D.D., *Chairman*; Revs. P. Fairbairn, D.D., and J. Kadie, D.D., LL.D., Professor Nichol, Messrs. J. Gourlay, A. H. Dick, M.A., J. McIntosh, J. Seligmann, J. Mayer, F.C.S., W. Neilson, W. McOnie, J. Macintyre, A. H. Maclean, Alex. J. Blair, Daniel McLaren, L. C. Alexander, Gordon Smith, Robert Legatt, John Dansken, and John Allan, Inland Revenue, 18, Queen-street, *Secretary*.

GLASGOW INSTITUTION.—Alex. Strathern, Esq., Sheriff-Substitute of Lanarkshire, *Chairman*; Revs. George Jefferey, D.D., Norman McLeod, James Macgregor; Rev. James Mackay, and H. S. Paterson, M.D., *Vice-Chairmen*; Messrs. Geo. Anderson, *Treasurer*, James Cockran, Robert Dalgligh, M.P., John Dickie, F.E.I.S., Duncan Fletcher, F.E.I.S., D. B. Hutcheon, F.E.I.S., Rev. John Isdale, Mr. H. A. Lambeth, Rev. William Leggatt, Messrs. James McBurnie, M.D., Arch. McTaggart, M.A., John Meikleham, Thomas Menzies, F.E.I.S., Kenneth M. Miller, F.E.I.S., Thomas Morrison, M.A., John Mosman, William Mossman, Rev. Walter Muckersie, Messrs. Thomas Neil, Bailie Alex. Osborne, Rev. George Pantou, Dr. F. Penny (Professor of Chemistry), Messrs. Bailie, Jas. Salmon, David Smith, J.P., Rev. W. C. Smith, Messrs. Robert Somers, A. C. Weir, F.E.I.S., James Wilkinson, James Wyllie, F.E.I.S., and John Craig, F.E.I.S., Glasgow Institute, 280, George-street, *Secretary*.

GLASGOW MECHANICS' INSTITUTION.—Dr. T. Anderson, Dr. Caird, Sir W. Thomson, Dr. Allen Thomson, Professor Nichol, Dr. Walker Arnott, Dr. Bryce, Rev. Dr. Taylor, Messrs. J. Young, W. H. Lithgow, T. McFarlane, J. Couper, Daniel Macnee, D. More, J. Inglis, and J. K. Dempster, *Secretary*.

GLASGOW, POPULAR EVENING CLASSES ANDERSONIAN UNIVERSITY.—Mr. Wm. Euing, *Chairman*; Drs. A. Thompson, F. Penny, G. Buchanan, Laing; J. Taylor, Rev. John Curwen; Messrs. W. M. Neilson, M. Fryar, R. Kennedy, C. H. Wilson, A.R.S.A., R.I.A.A. Harvey, J. W. Guild, R. S. Cunliff, A. S. Herschel, C. Brown, Wm. Tait, E. Wünsch, G. Norval, D. Currie, G. Lang, J. Thomson, W. R. McLean, Wm. Combe, and G. Martin, 11, Great Western-road, *Secretary*.

HALIFAX MECHANICS' INSTITUTION.—Messrs. Henry Hill, J. H. Child, James Walton, and A. C. Foster, *Secretary*.

HALIFAX WORKING MEN'S COLLEGE.—Lt.-Col. Akroyd, M.P., *Chairman*; Rev. C. R. Holmes, M.A.; Messrs. H. Akroyd, Ridgway, M.A., J. E. Champney, J. W. Garlick, M.D., J. McKirk, J.P., C. N. Wilkinson, T. Midgeley, T. Cordingley, S. Hartley, J. C. Wainhouse, Middlebrook, W. Longbottom, G. Parker, and G. Gibb, Halsey-hill, Halifax, *Secretary*.

HASTINGS AND ST. LEONARDS.—Mr. C. J. Womersley, *Chairman*; Dr. Moore, Rev. J. Porter, Mr. Jas. Rock, Mr. Alfred Burton, Dr. E. D. Hale, Mr. Butler, Revs. S. Hadden Parkes, Foyster, Halley Stewart; Messrs. Lindridge, Banks, Gibson, and Mr. J. Charles Savery, 27, Marina, St. Leonards-on-Sea, *Secretary*.

HARROW BRIDGE.—Rev. Henry Thomas, M.A.; Mr. William Pateman, and Rev. William Baldwin, M.A., *Secretary*.

HERTFORD.—Robert Dimesdale, Esq., M.P., *Chairman*; Rev. Thos. Lander, M.A., *Vice-Chairman*; the Hon. Hy. Cowper, M.P., Wm. Clinton Baker, Esq.; Revs. Canon Blakeley, B.D., — Chittenden, B. Higgins, Charles Deedes, N. Keymer, T. L. Lingham, J. B. Moore, Charles Thornton, H. L. Warleigh, J. W. Birch, R. P. Davies, and John Davey; Revs. W. Gill, Arthur S. Latter, W. W. Harries, W. Hankin, — Barker; Messrs. Y. Crawley, S. H. Errington, J. L. Foster, H. Gilbertson, J. W. Grove, G. Hancock, J. T. Hannum, J. Marchant, D. Peirson, H. Robins, H. Squire; John Lyon Foster and the Rev. John Davey, Hales Grammar School, *Joint Secretaries*.

HOLBOCK (LEEDS).—Mr. William Packer, *Chairman*;

Rev. H. N. Sumner; Messrs. Joseph Leathley, Joseph Matthews, — Samwell, John Wilkinson, and George Tinker, *Secretary*.

HUDDERSFIELD MECHANICS' INSTITUTION.—Edward Huth, Esq., *Chairman*; Messrs. John Dodds, John Sugden, Joseph Lowenthal, George W. Tomlinson; Joseph Bate, Mechanics' Institution, Huddersfield, *Secretary*.

HULL.—Revs. R. A. Redford, M.A., LL.B., *Chairman*; A. Jukes, B.A.; Messrs. J. H. Gresham, T. D. Ball, G. Raven, and P. Blackmore, 2, Charlotte-street, *Secretary*.

HUN-LET (LEEDS).—Messrs. Peter Gilston, James Yewdall, John Parker, H. B. Atkins, J. Bramham, S. Jennings, J. G. Teal, C. J. Dawson, and W. Child, Powell-street, Hunaleet, *Secretary*.

IPSWICH.—E. Christian, Esq., Ph.D., *Chairman*; Revs. J. R. Turnock, F. H. Maude, T. M. Morris; Messrs. J. Evans, H. Footman, A. Lambert, C. F. Gower, R. Everett, H. G. SMETHWICK.—Mr. F. Talbot, Messrs. Chance's Schools, Smethwick, *Correspondent*; Revs. T. G. Simcox, R. Ferguson, H. Stowe, Messrs. W. E. Chance, T. Mallin, T. Townsend, G. Downing, E. Morris.

STOURBRIDGE.—Rev. H. Sherrard, Stourbridge, *Correspondent*; Revs. J. Welch, J. Richards, D. Maginnis, Messrs. J. Taylor, W. Akroyd, W. England, Joseph Maurice, C. Evers, T. Southall.

WALSALL.—Rev. J. Bradley, Walsall, *Correspondent*; Revs. Dr. Gordon, Messrs. F. Crump, H. Eagles, J. Vaughan, J. Pritchard, C. Ivons, W. A. Dunston.

WADNESBURY.—Mr. C. Britten, Market-place, *Correspondent*; Rev. J. Winter, Messrs. J. T. Bailey, R. Williams, J. Bailey, T. Southern, R. Gray, S. Z. Lloyd, T. Quelch, W. Hardy.

WEST BROMWICH (1).—Rev. F. P. Hutton, Gold-hill, West Bromwich, *Correspondent*; Revs. F. Willett, C. Massey, Messrs. W. H. Bagnall, W. S. Naylor, T. Underhill, R. Haines, Jos. Naylor.

WEST BROMWICH (2).—Rev. J. Whewell, West Bromwich, *Correspondent*; Messrs. T. Crabtree, J. Cooksey, J. Hall, T. Davies, J. Ward.

WILLENHALL.—Mr. J. C. Tildealey, Willenhall, *Correspondent*; Revs. G. H. Fisher, W. Fletcher, M. Hathaway, J. Stevens, Messrs. Ley, L. Chapelle, J. Bennett, J. Webb.

WOLVERHAMPTON (1).—Mr. J. N. Langley, Mor-bray-house, Wolverhampton, *Correspondent*; Rev. J. H. Iles, Messrs. T. Beach, W. Y. Brevitt, W. M. Fuller, Herridge, Houlit, Butt.

WOLVERHAMPTON (2).—Mr. George Bidlake, *Correspondent*; Messrs. H. Gibbs, W. M. Fuller, W. Mitchell.

SOUTHERN COUNTIES ADULT EDUCATION SOCIETY.—Messrs. J. Moyer, M.P.; C. A. Raikes, Hon. and Rev. S. Best; Revs. Dacres Olivier, H. E. Ravenhill, R. Fitzgerald; Rev. J. Monkhouse, Oakley, Basingstoke, Secretary.

STOCKSBRIDGE (SHEFFIELD).—Rev. H. Robertshaw; Mr. J. Hepworth, and Rev. H. Robertshaw, Secretary.

STOCKTON.—Messrs. Joshua Byers, J. Bennington, T. Crosby, T. Ainsworth, F. Sanderson, and T. W. Hornsby, Secretary.

SWINDON (NEW).—Mr. Joseph Armstrong, C.E., President; Messrs. Samuel Carlton, M.E., John Holmes, R. L. White, George F. Swinhoe, M.D., Geo. F. Ellis, J. Haydon, W. Ellis, J. H. Preece, and W. L. Fallows, 22, Bridge-street, New Swindon, or the Institution, Honorary Secretary.

THIRSK.—Revs. E. Jowett, H. Howard; Messrs. J. Rider, T. Alderwick, W. A. Bourne, T. Scott, and Richard D. Carter, Secretary.

WAKEFIELD.—The Rev. J. S. Eastmead, Chairman; Messrs. G. Mander, J. Binks, W. S. Banks, S. Bruce, Wm. Ash, and P. W. Paver, and William Ash, Mechanics' Institution, Wakefield, Secretary.

WATFORD.—Dr. J. Caret, M.D., Chairman; Dr. J. F. Scott; Messrs. David Keogh, Woodward Mason, William Godbey, and Mr. James Budd, 5, King-street, Watford, Secretary.

WELLINGBOROUGH.—Mr. Benj. Dulley, Chairman; Revs. H. V. Broughton, M.A., (Vicar), H. M. Roxby, M.A., J. F. Poulter, B.A., Messrs. William Dulley, jun., Wm. A. Rabbra, M. Reid Sharman, Edward Sharman, W. R. Harrington, and T. S. Curtis, Hon. Secretary.

WEST HARTLEPOOL.—Rev. H. J. Martin, Messrs. Isaac Bowes, James K. Anderson, Henry Casebourne, T. P. Branton, Robinson Murray, William Hunter Fisher; Charles Townshend Casebourne, C.E., and John Legbourne, Hon. Secretaries.

WHITBY.—Rev. W. Keane, M.A., Chairman; Dr. Dawson; Rev. J. Owen; Messrs. Stonehouse, J. Bate, and W. G. Chiesman, Secretary.

WILDEN (BINGLEY).—Rev. J. Parnaby; Messrs. Thomas Wadsworth, Abraham Ambler, Fras. Butterfield, and C. Petty, Secretary.

WOOLWICH ARSENAL.—Mr. Anderson, Chairman; Messrs. Oram, Fullom, Baker, Davidson, Tozer, Millard, Spiller, McKinlay, McGrath, and W. D. Keeble, Royal Laboratory, Royal Arsenal, Woolwich, Secretary.

WOOLWICH (ST. THOMAS' PAROCHIAL SCHOOLS).—Capt. R. Robertson, R.N., J.P., Chairman; Rev. A. De La Mare, M.A., Rector; Capt. A. Harrison, R.A.; Messrs. Jno. Carless, M.D., E. Brough Sargent, Jno. McArthur, Thales Pease, J. E. De La Mare, H. Shersby, G. Craig, and J. H. Norman, Secretary.

WORCESTERSHIRE UNION OF INSTITUTES.—John Slaney Pakington, Esq., President; Mr. F. Marcus, Worcester, Secretary.

BAWDLEY AND WRIBBENHALL.—Rev. J. Fortescue; Messrs. Nicholls and Birtwistle.

BROMSGROVE.—Messrs. W. Holyoake, Laughton, G. W. Gibson, Dodd, and Dunn.

DEBITWICH.—Messrs. Jeacock and Causier.

DUDLEY.—Rev. R. Harper; Messrs. E. Hollier, J. Wood, J. F. Timmins, Minty, S. Waring, Crompton, Williams, J. Williams, and Bagshaw.

EBLEY.—Messrs. H. Webb, G. Hyatt, and H. Jefferies.

EVESHAM.—Rev. M. Wood; Messrs. H. New and W. Smith.

HANLEY CASTLE.—Rev. P. Kingsford; Messrs. A. Shewell and J. Holder.

KIDDERMINSTER CHURCH OF ENGLAND MUTUAL IMPROVEMENT SOCIETY.—Rev. W. Packe and Mr. Starr.

KIDDERMINSTER MECHANICS' INSTITUTE.—Messrs. H. Fawcett, J. Hopkins, and J. Greenwood.

MALVERN.—Drs. Marden and C. A. Mason; Mr. Fernie.

REDDITCH.—Messrs. V. Milward, G. C. Richards, and W. T. Heming.

STOURBRIDGE ASSOCIATED INSTITUTES.—Rev. D. Maginnis; Messrs. J. Taylor and R. Southall.

STOURBRIDGE CHURCH OF ENGLAND INSTITUTE.—Revs. H. Sherrard, J. J. Welch, and T. Williams; Messrs. E. W. Bernard, J. Gething, A. Freer, Goddard, W. Cooper, J. Doughty, T. W. Pardoe, and J. Fowler.

STROUD.—Messrs. S. S. Dickinson, J. Sibree, and W. Grist.

WORCESTER CATHOLIC INSTITUTE.—Rev. W. Waterworth; Messrs. J. Tree, F. Reeve, and W. Allen.

WORCESTER CO-OPERATIVE READING-ROOM.—Messrs. Smith and Conn.

WORCESTER BIRDPORT FREE CHURCH MUTUAL IMPROVEMENT ASSOCIATION.—Messrs. E. J. Lewis, J. P. Baylis, A. Whittall, Hurcombe, and E. Powell.

YORK.—Rev. H. V. Palmer, Chairman; Messrs. W. Gummerson, C. Sellers, H. Wilson, W. Bartle, J. Holtby, and Robert Hall, 8, Feaigate, York, Secretary.

THE AGRA EXHIBITION.

In continuation of the history of this exhibition of the North-West Provinces of India, which has already appeared in the *Journal* (see pp. 181 and 265), the following account of the closing is condensed from the local papers:—

The Lieutenant-Governor officially closed the Exhibition on Saturday, the 9th February, when the ceremony was performed in the open air. He made a speech, showing how these industrial exhibitions excite an interest among the natives of all countries. After a few lines of exordium, he proceeded to say:—

"To all those who have seen this exhibition, it will, I doubt not, have commended itself, by its intrinsic excellence, far more effectually than any words of mine could hope to do, but I do not fear to say that, looking at the means at our command, and the cost which has been incurred, no more effective effort has yet been made out of Europe, to realise the true objects of such an undertaking; for not only have we here an admirable collection of the most valuable and interesting articles in almost every department of industry and art, but we have also, in the buildings and grounds and general arrangements, a most striking and practical exposition of the almost magical facility and rapidity with which well-directed energy and skill can transform the common things around us, the raw materials, the barren plain, into the most harmonious combination of utility and ornamentation, which at once instruct and gratify the taste and the imagination, and by their practical usefulness materially contribute to the real progress of the objects we have in view. All honour, then, to those to whom we are so greatly indebted for the success which has now been achieved. To yourself and the gentlemen of the Central Committee I have already expressed my obligations. I desire now more particularly to thank Mr. Sibley for the design of the central building, which, with the skilful aid of Mr. Cole, has formed the principal feature of the exhibition, and has certainly excited as much wonder and interest in the minds of the natives, as the more costly contents which it protects. To the Board of Agency, E. I. R., I would express my acknowledgments for the readiness and liberality of their assistance. To the exhibition staff, who have borne the burden and heat of the day, whose labours have been as unceasing as their anxieties, and only to be gauged by the success which has attended them, no words of mine can adequately convey the commendation which I feel to be their due. Mr. Pollock, Colonel Rowlatt, Dr. Playfair, Mr. James Simson, Dr. Moir, Lieutenant Cole, Mr. Webb, and Mr. Adams, have each and all fulfilled the task entrusted to them with a degree of ability and success which cannot be too highly praised. Most cordially I thank them one and

all. I consider the general result of their efforts to be deserving of the highest prize for merit of all that has been here exhibited. I hope to convey to them hereafter a separate memento of the occasion; that highest prize, which is, I doubt not, that which they covet most, success, and the public appreciation and acknowledgment of that success, is theirs now. To Mr. Pollock belongs the merit of the chief executive control and organisation of the whole exhibition. I desire especially to acknowledge and to thank him for the ability, unwearied perseverance and determination to succeed, the energy and forethought, the zeal and talent for organisation which distinguished his management and assured our success. To Colonel Rowland we are most especially indebted for the wonderful creation of the gardens, the tasteful ornamentation of the grounds, the band-stand, fountains, and many other evidences of taste, and fertility of resource, to which so much of the success of the exhibition is due. Among other things, for the musical part of the opening ceremony, which added so much to our gratification, and for which I would take this opportunity of offering my grateful thanks to the ladies and gentlemen who joined so kindly and effectively in its execution. To Lieutenant Cole we are under the greatest obligations for the beauty of the Central Hall, its internal decorations and artistic embellishment, the tasteful machinery sheds, and many other parts of the arrangements. We have been most fortunate in obtaining his services, of which I hope we may have the opportunity of still further availing ourselves, for the purpose of securing a permanent record of this exhibition. I cannot speak too highly of what has been accomplished by these gentlemen in the unity and simplicity, the elegance and taste, of all the arrangements of the structures and the ground. I desire also here particularly to notice with marked commendation, the valuable and effective services of Mr. Robinson, the Secretary to the Municipal Commissioners of Agra. To the Municipal Commissioners, to the several members of the mercantile community of Agra, and to the Tuhaseeldar, my acknowledgments are due for zealous and liberal aid. The assistance rendered by the Governments of Bombay, of Bengal, and of Madras, the very valuable contributions of Mr. Temple, from the Central Provinces, of Mr. Justice Phear, Dr. Hunter, and many others named in your opening address, deserve a more ample recognition than time will at present allow me to give them; to all I desire to return my most hearty thanks. To Mr. Temple and Mr. Dowleams we are more especially indebted for most effective aid, and I regret that circumstances have prevented our seeing them among us this day. I have to acknowledge the very hearty and able assistance which this exhibition has received from so many of my native friends, from the chiefs, the local committees and gentry generally of the country. I trust that they have not only been amused, but have profited by the exhibition. I am sensible that it has occasioned many of them an amount of trouble and expense, which must greatly enhance our estimate of the liberality with which most of them have supported it. It is most satisfactory to me to feel that this aid has not unfrequently been given from a true appreciation of our objects and a real desire for the practical advancement of the people."

The Lieutenant-Governor then proceeded to name those especially among the native gentlemen who were the most distinguished in aiding the undertaking, and concluded as follows:—

"I must add a few words upon the great success of the experiment of free admissions, upon which many doubts were entertained. Nothing could have been more orderly than the crowds which have daily flocked to the grounds, and it is remarkable how intelligent has been the appreciation generally of the exhibition; the wonderful crowds of women and of children evincing the perfect confidence of the people. There has been no mischief or damage of any kind. The practical remark

has been that they have not time enough to study what they see, a real drawback, which it will be my endeavour to remedy in some measure by a well-prepared catalogue of the articles, which may hereafter be translated into the vernacular. I will only add a few words of commendation of the police and sanitary arrangements, the former under the immediate direction of Captain Dennehy. All have been most excellent, and reflect the highest credit upon those who have organized them. I believe there has not been a single case of loss of property. And now, before concluding, I must say a few words of acknowledgment to all around me, and to the visitors generally, for the large measure in which they have contributed by their presence and demeanour to the success of the exhibition. Hitherto on such occasions the difficulty has been to get the people to come. Now all press in of their own accord. There have been no complaints of any kind; on the contrary, I am told that all are thoroughly satisfied, and speak in high terms of the courtesy and consideration with which they have been treated. I regret that our meeting has been so brief. I trust, however, that while many have benefited, all have been gratified by what they have seen during the past week, and that they will retain a pleasant recollection of this exhibition. Such an event is not likely to recur in these provinces for some years to come—local associations will be left to work up to the present model. I trust, however, that the next that may be held, whether organised by government, or by private enterprise, may as much excel the present as this surpasses previous efforts; but, however that may be, it cannot, I think, prove more creditable to those who execute it, or more successful in its immediate effects. I now declare the Exhibition closed."

OPENING OF PUBLIC AND PRIVATE COLLECTIONS DURING THE PARIS EXHIBITION.

The Museum of Antiquities in the Louvre, at which that portion of it which is contained in the ancient apartments of Anne of Austria, beneath the Galerie d'Apollon, has been completely renovated and re-arranged, and opening has been announced.

The new library and reading-rooms of the Bibliothèque Imperiale are finished, or nearly so, and to be opened during the present month. By the new arrangement there will be a common reading-room for the people open to all the world, according to the practice of the institution, and a second reading-room, with much greater facilities for reference and study, for masters, letters and students. The innovation will present a subject deserving of study and consideration, for giving of more facilities to literary men, without detracting from those of the public, is a problem that is well worth the trouble of solving.

Prince Napoleon throws open his artistic collections at the Palais Royal to the public five days a week, during the exhibition season; cards of admission to be obtained by application in writing, addressed as follows:—"à M. Hubaine, secrétaire particulier de Son Altesse Impériale, or, "à M. Brançon, intendant, Palais Royal, cour l'Horloge."

The announcement of the opening of the museum arms and ancient armour, lately formed in the rest of the château of Pierrefonds, is confirmed. The early part of May is the time fixed upon. Excursion trains will be arranged for the same period. A visit to Pierrefonds will have other attractions besides the new museum. Château is one of the feudal castles of France, restored by M. Viollet-le-Duc, and the country around is fine.

The great new park of the Buttes Chaumont opened on the 1st inst. This pleasure-ground is of great extent, and occupies the site of the old plaster quarries, the irregularities of which have been turned to picturesque account. The chief objects of interest are the production of the Temple of the Sibyl, and a fine waterfall, lakes, and canal; there are five bridges,

utiful light specimen, on the suspension principle, 3e restaurants, six ornamental houses and lodges for keepers, some of them decorated with *faïences*, 3tco, three plateaux, commanding fine views, and a and planted with fine cedars. The circular railway ses through the new park.

Fine Arts.

ART AT THE PARIS EXHIBITION.—The picture gales contain for the most part a fair and full representa- n of national schools throughout the world. Four rters of the globe and twenty-four countries are pre- t. France, being at home, has peculiar facilities, and ibits at her very best. Still, since the last Universal position, in 1855, she has lost several great painters, ose pictures are now specially missed. Ary Scheffer, res, Delaroche, Delacroix, Horace Vernet, Troyon, Decamps can no longer be present in International hibitions. As a consequence, the character of French is changed. Instead of pictures large and life-size, place of works after the prescriptive type of high and toric styles, the tendency now is to compositions of nance and fancy. The most prominent exceptions ne under the names of Yvons and Pils, who celebrate glory and martial deeds of the empire. The English olic have at home, in the galleries of Mr. Gambart l Mr. Wallis, become acquainted with the leading its of the existing French school. Still, seldom have n collected at one time so many *chefs-d'œuvre* of lead- ; contemporary painters. By Rosa Bonheur there are ven pictures, by Gérôme seven, by Meissonier eleven, Frère eight, by Hamon also eight, by the late M. oyon seven, by Zeim four. These names and numbers icate that the 625 pictures which constitute the gal- y represent the French school in its strength and eadility. Two hundred and thirty painters, each of om has already acquired acknowledged position, are sent. Nevertheless, perhaps, as a grand national play the effect is a little scattered when compared th the Universal Exposition in 1855. Then were neentrated in separate rooms the noble and vast works Ingres and Horace Vernet. No such climax is now ached. Nevertheless, it will be admitted that the rench courts contain a full and faithful register of the tional school, and that they present to the student a re opportunity of forming a just judgment on the aracteristics of French art. The same, too, may, with tile reservation, be said of the choice though small col- ction of English pictures. Many names, it is true, are sent. Two leading painters, for example, who repre- nt landscape art in the Royal Academy—Creswick and e—are not represented. Still, in the works of Linnell, ther and sons, of Stanfield, Graham, and MacCallum, e supremacy of English landscape is fairly maintained. 1 other departments are recognised such well-known orka as Elmore's "Tuileries," Phillip's "Gloria," or ice over a death, "Poole's "Song of Philomene on ie borders of the beautiful lake," Millais's "Romans itting Britain," Lewis's "Coptic-court, Cairo," 'Neil's "Eastward, Ho!" Armitage's "Queen Esther," Vallis's "Death of Chatterton," and Hunt's "After- low, Egypt." With the exception of the last, all these ctures were first known to the public in the Royal cademy. The art of water-colour painting, in which ngland is supposed to be supreme, is also tolerably e-rented, though, from the reluctance of owners to llow valued works to leave the country, far less fully han in London in 1862, or at the Art Treasures, Man- hester. Well-selected works have, notwithstanding, een obtained of many leading masters, such as Cox, Davidson, Gilbert, Haag, Haghe, Holland, W. Hunt, malfield, Tayler, Tidey, Topham. The total number f oil pictures and water-colour drawings in the English

court is 300, or less than one-half the total in the French; this, if numbers were the only criterion, would give to England an adequate proportion, seeing that France oc- cupies not less than one-half of the entire building. The large size, however, of French pictures generally still further gives to France the advantage over any other nation. The preceding data will indicate the ex- tent, variety, and value of the contents of the picture galleries. We shall add from time to time further evi- dence of the extraordinary art riches and resources of an exhibition which, because found in an unfinished state, has not been appreciated at its high worth.

Manufactures.

DIAMOND BORING MACHINE.—The diamond has been frequently used for turning up porphyry and other hard stones; the late M. Leschot, in 1862, took out a patent for the employment of this mineral in boring hard rocks. Every one knows the difficulty of boring stone of an exceptional hardness with ordinary tools. The work is excessively slow, and it is with difficulty a passage is opened. It appears that the employment of the dia- mond has completely changed this state of things, and has allowed working with rapidity in circum- stances where the employment of ordinary means would have rendered the work to be accom- plished almost impossible. In following the process of M. Leschot, M. Pichet has constructed a bor- ing machine of great power. It is composed of a steel ring set with black diamonds. In order to use this apparatus it is only necessary to make the ring rotate, and press against the rock to be perforated. It is easy to understand the action of the apparatus; the diamond grinds the stone, and consequently, by means of its circular motion, a cylindrical ring of rock is re- duced to powder. A current of water carries away the fragments of the boring as quickly as they are produced, so that the work is proceeded with very rapidly. The borer does not hollow out a hole in the stone, but a cylindrical ring, the adhering core of rock then re- maining in the tube, can easily be detached by the blow of a mallet. It is easy to see that, only having to powder a circular ring of rock, the motive power need not be considerable, and the length of the operation would not be great. M. Pichet's apparatus is now being employed at the tunnel of Port Vendres; it is moved by hydraulic power, and by its use it is said that 1·2 metre of rock is pierced per hour. The black dia- mond employed for this operation wears but little, and when it can be no longer used for the purpose it is re- duced to powder, and employed in polishing precious stones.

COAL MINES IN POLAND.—Borings are continued the whole length of the railway lines in the kingdom of Poland; these operations, which have already led to the discovery of four seams of coal, have now obtained a still further success, as a fifth seam has just been found at Dombroff, and a sixth in the forest of Stohemeschiton.

Commerce.

TEA CULTIVATION IN INDIA.—The unsatisfactory state of tea cultivation in India at the present day (says the *Produce Markets Review*), and the unfortunate condition of the planters, after having been freely commented upon in all quarters, seem at last to have come under the notice of the Indian Government; and acting upon certain representations which have been made to him, the Lieu- tenant-Governor of Bengal proposes that some concession should be held out to the tea-planters, in order to enable them to retrieve in some measure the losses which they have been incurring for some years past. The remedy suggested, "that purchasers of lots under Waste Land

Rules, who have not completed the payment of the purchase money, should be allowed to throw up one or more of their lots, and to carry the amounts already paid as instalments to the credit of other lots of waste land," does not seem sufficient either to obviate the real difficulties with which the question is beset, or to afford to planters the relief they so much need. Indeed the whole measure is characterised by a hesitating and uncertain irrelevancy which is calculated to call forth the opposition of all parties. Many aver that, as a private speculation, tea-planting should be left to take its chance of commercial success with all other schemes carried on by individuals; but we would suggest that the very nature of the undertaking elevates it from the list of private enterprises to the dignity of a question in which an almost national interest is created. Those, however, who find fault with the insufficient character of the relief in prospect, should remember that in this apparently small instalment a principle is involved, and that when once the condition of the planter is made the subject of official inquiry, the labour question and its direct bearing on the planter's interests are necessarily involved. Hitherto the sympathies of the Indian Government, so far as they could be said to be enlisted at all, have undoubtedly been on the side of the "coolies;" and, whilst nothing was too bad to be laid at the door of the employers of labour, everything was to be done in favour of the employed. Laws were passed; special officers appointed; extraordinary means were taken—all to secure the well-being and prosperity of the "coolie;" whilst the planter—it was tacitly inferred—might safely be allowed to trust to his own resources so far as regarded his tea-planting career, and be left to make the best shift he could against the overwhelming odds of a race of labourers steadily backed by the whole weight of Government authority. The turn of events during the last few years has shown how widely the Government has erred in this matter, and how important for the general good all protective measures must be designed to elevate one class at the expense of any other. These views, as we learn from the *Calcutta Englishman*, have lately been put forward with great cogency by the commissioner appointed by the Bengal Government to inquire into the condition of coolie labour in Assam and Cachar. "Had the commissioner," remarks the *Calcutta Englishman*, "been a planter himself, he could not have expressed himself in stronger language or more to the purpose; in almost every paragraph he condemns legislative interference." The commissioner avers that the labourer should be treated as a free agent, and that he ought to be left to make his own terms with the planter, whose real interest it would always be to maintain his labourers in the highest degree of health and efficiency. On these grounds he would recommend the unconditional repeal of all laws regulating the rate of wages, conditions of living, &c., leaving these matters to be settled by contract between the parties themselves without any official interference or supervision. "You can no more make tea grow," he remarks, "by Act of Parliament, then you can make an unwilling or unworthy man provide for the proper discharge of his duty by penal laws." As soon as these views are understood and accepted by the Indian Government the planters will have some prospect before them of recovering their losses; but it is useless to expect any improvement whilst the impediments to their free course are so eagerly taken up, and so sedulously fostered by those who hold the rule and the prosperity of India in their hands.

Colonies.

BORDER DUTIES, VICTORIA AND NEW SOUTH WALES.—The vexed question of these duties has been arranged by an intercolonial conference held at Melbourne. The Victorian Government have undertaken to pay New South Wales £60,000 per annum for five years, and

£6,800 arrears due since 1864. Free trade in the products of either colony is also guaranteed while the treaty is in force. By this new arrangement the Victorian merchants are secured the import and export trade of the whole of the Riverina, without that anxious competition with South Australia which they have hitherto had to compete with.

NEW SOUTH WALES REVENUE.—The total revenue of this colony for the year 1866, exclusive of loans and special receipts, was £2,038,079. As there are about 400,000 people in the colony, this shows that the revenue obtained is at the rate of about five pounds a head. The increase on that of last year is £263,904. Of this no less than £248,636 is due to Customs alone, that the other sources of revenue have had very little to do with the restoration of the public credit. The Customs revenue gives a shade over £2 per head of the population. Two-fifths of the whole, therefore, comes from it, and indeed, with the exception of licenses, it is about all that can be properly called taxation; and of this amount very nearly one-half is duty on intoxicating liquors. The new tariff has increased the revenue from spirits, and also from ale and beer. The taxes on tea and dried fruits also bring in nearly £20,000 a year. The duties on tea and sugar yielded £96,000, and this was £30,000 below the yield of the previous year, as was much below the estimate—a fact due to goods taken out of bond in anticipation of an enhancement of duty. The revenue of the Post-office is £77,000, which is an increase of £6,000 on the revenue for 1865. The railway receipts were £176,246, which is an increase of nearly £13,000 on the return of the previous year, and an advance of over £4,000 on the estimate. The telegraph receipts are nearly £34,000, which is somewhat over the estimate, and an advance of over £3,000 on the previous year. The total disbursements for the year amount to £2,100,820, being a little over the income.

GOLD DISCOVERY IN QUEENSLAND.—The government of Queensland has offered a reward of three thousand pounds to any person or persons who shall, individually or jointly, make discovery of a gold field situated at least twenty miles distant from any gold field already proclaimed within the colony. Such reward will be payable as soon as it shall be shown that the field so discovered has attracted to it, and supported for the space of six months, a population of not less than 3,000 persons.

PROGRESS OF NEW SOUTH WALES.—The progress of the colony of New South Wales during the last twenty years has been far greater than was anticipated at the commencement of it. In the year 1846 the population was less than 200,000, which included the districts Port Phillip and Moreton Bay. The following are the statistics. There were in

	1846.	1866.
Schools.....	394	1,069
Scholars.....	19,033	53,453
Mills.....	138	175
General.....	124	—
Manufactories....	—	2,133
Tillage area.....	183,360 acres	379,254 acs
Horses.....	88,126	282,587
Horned cattle....	1,430,736	1,961,905
Sheep.....	7,906,811	8,132,511

Twenty years ago New South Wales was unknown as a gold-producing country, but it now exports that metal to the extent of £2,647,668. This state of prosperity was indeed in the second year of its auriferous development, and it has not yet in any year much exceeded the amount then reached; but during the next twenty years a greater increase may be expected, as machinery is increasing, and the mining appliances are at present rude and wasteful. There is an immense increase in the expenses. In 1846 this was £290,000, and it has in 1866, reached £2,314,794. This latter sum includes the loan expenditure, but it shows how large a sum the government annually expends, being at the rate of

nearly £8 per head of the population. Even without the loan expenses the expenditure exceeds £4 per head.

WINE-GROWING IN VICTORIA.—The consumption of colonial wine is rapidly increasing, and if the next vintage proves equal to the present anticipations, colonial wine will be placed in the market at a price and of a quality that only France can compete with. In 1866 the wine cultivation increased from 1,307 acres to 18,063 acres. The number of vines of three years and upwards increased from 3,109,735 to 3,781,169, thus 671,414 additional vines came into bearing during the year. The grapes gathered amounted to 49,749 cwt., of which 31,686 cwt. were made into wine or brandy, producing 176,959 gallons of the former, and 795 of the latter. The land under other crops last year amounted to 1,705 acres, against 1,264 in 1865. The area under garden cultivation, was 6,654, against 6,627 acres; and orchards 3,419 acres, against 2,364 acres in 1865.

Obituary.

M. HITTORF, an architect of deserved reputation, and many years occupied with government works, died recently in Paris at the age of 74. He was pupil of Percier and Belanger, and made himself remarked by his attempts to restore polychromatic architecture. His principal works of this class are the church of St. Vincent de Paul and the circus in the Champ Elysées. He arranged the Place de la Concorde, the place of the Arc de Triomphe, and built the new Paris terminus of the Northern Railway. M. Hittorf was a member of the Academy, and author of works on the architecture of ancient and modern society, on the polychromatic architecture of Greece, and on the antiquities of Attica. The last has been published in English.

Notes.

PNEUMATIC DISPATCH BETWEEN THE BOURSE AND THE GRAND HOTEL IN PARIS.—This tube is the commencement of a system which is to extend under ground throughout Paris, based on a principle which up to the present time has not been applied as a useful means of propulsion. It is not the atmospheric pressure which acts on the piston from behind with a vacuum in front, but it is the elasticity of compressed air which supplies the necessary propelling force, and this process gets rid both of an exhausting machine and the steam power. The compression of the air is obtained by means of water furnished by the reservoirs of Paris, the power of which is equivalent to a head of 15 metres. To produce the result three vessels of sheet iron, each holding 4,500 litres, are fixed; the first is intended to receive the water and to give the pressure, the two others receive the compressed air. A large cock allows the water brought from the subterranean pipes to penetrate. As the vessel fills, the air which it contains is compressed and driven back into the two others, in passing through a tube furnished with a valve which prevents its return. When the water has entirely filled the vessel, it is allowed to run out by a second cock, whilst a valve applied to the upper side, which is lowered by means of a lever, allows the outer air to enter as the water runs out. By filling the vessel a second time with water, a fresh quantity of air is added to that already compressed, and a pressure of about two atmospheres is thus obtained. The two offices are connected by a cast iron tube about 1,060 metres long, the interior diameter, 2½ inches, opening at each extremity into an hermetically sealed chamber by a door which allows the introduction or withdrawal of the piston carrier containing the dispatches. This pis-

ton consists of a hollow brass cylinder, 5½ inches long at one extremity, and furnished at the other with a moveable lid. It will hold about 40 dispatches placed in envelopes. Before sending off a dispatch an electric bell gives a signal to the correspondent at the opposite end, who answers by signal that the way is clear, that is to say, in communication with the outer air. The cylinder containing the dispatches is placed in the opening of the tube, which is closed by the turn of the handle, and communication is made with compressed air. The piston, smartly driven back, drives before it the air in the tube, and arrives at its destination in about 60 or 80 seconds. Whilst one station gives the pressure, another can send the message, so that 5 minutes is sufficient for a journey and return of the piston. This system obviates stoppages between stations.

MEETINGS FOR THE ENSUING WEEK.

Mon......London Inst., 7. Prof. Westwood, "On Entomology."
Tues ...Medical and Chirurgical, 8½.
Ethnological, 8. 1. Dr. Collingwood, "Visit to the Kibalan Village of Sano Bay, north-east coast of Formosa." 2. Mr. John Crawford, "On Colour of the Skin, Hair, and Eyes, as a Test of the Race of Man."
Wed ...Society of Arts, 8. Mr. S. J. Mackie, "On the Construction of Iron Ships, and their Preservation by Zinc Sheathing."
London Inst., 12. Annual Meeting.
Microscopical, 8.
R. Society of Literature, 4½. Annual Meeting.
Archæological Assoc., 8½.
Thurs ...London Inst., 7. Prof. Bentley, "On Botany."
Mathematical, 8.

Journal of the Society of Arts.

FRIDAY, APRIL 26, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

LAY 1.—“On a Machine for Type-writing.” By
IN PRATT, Esq., of Alabama, U.S.

CANTOR LECTURES.

Mr. HULLAH's course, “On Music and Musical
struments,” will be extended by two additional
tures, as follows:—

LECTURE VII.—MONDAY, APRIL 29.

MUSICAL INSTRUMENTS (*continued*).—The Bow—The
y-board—The Violin—The Organ—The Clavichord.

LECTURE VIII.—MONDAY, MAY 6.

MODERN INSTRUMENTS, CHAMBER AND ORCHESTRAL.—
e Pianoforte—Combination of Instruments—The Or-
estra.

The concluding lectures of Mr. CHAFFERS'
urse, “On Pottery and Porcelain,” will be
livered as follows:—

LECTURE VI.—MONDAY, MAY 13TH.

ENGLISH POTTERY.—Fulham—Lambeth—Yorkshire
Shropshire—Liverpool—Staffordshire—Etruria—
edgwood's Wares, &c.

LECTURE VII.—MONDAY, MAY 20TH.

ENGLISH PORCELAIN.—Bow—Chelsea—Derby—Wor-
ster—Liverpool—Wales—Plymouth—Bristol—Lowe-
oft—and other Manufactories—Battersea Enamel, &c.

The lectures commence at eight o'clock, and
re open to members, each of whom has the
rivilege of introducing one friend; tickets for
us purpose are forwarded with the present
umber of the *Journal*.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling
ae importance of promoting the intelligent
tudy of the Paris Exhibition and the manufac-
uring establishments in France by artisans of
he United Kingdom, have appointed a Com-
mittee in furtherance of this object. The fol-
owing gentlemen constitute the Committee:—

Hon. C. B. Adderley, M.P.	Hon. and Rev. S. Best.
J. W. Aitken.	D. Robertson Blaine, <i>Memb.</i> of Council.
Edward Akroyd, M.P., <i>Vice-</i> <i>Pres.</i>	W. H. Bodkin (Assistant- Judge), <i>Vice-Pres.</i>
Sir W. G. Armstrong, C.B.	Sir J. P. Boileau, Bart., <i>Vice-Pres.</i>
L. S. Ayrton, M.P.	R. K. Bowley.
A. A. Beaumont.	Antonio Brady.
John Bell, <i>Memb. of Council.</i>	Rt. Hon. H. A. Bruce, M.P.
Professor Bentley, <i>Memb. of</i> <i>Council.</i>	Decimus Burton.
Lord Bernal, <i>Vice-Pres.</i>	C. Buxton, M.P.

The Earl of Caithness, <i>Vice-</i> <i>Pres.</i>	Rt. Hon. Robt. Lowe, M.P.
Lord Eustace Cecil, M.P.	Lord Lyttelton, <i>Vice-Pres.</i>
R. L. Chance.	Archbishop Manning.
Harry Chester, <i>Vice-Pres.</i>	Henry Maudslay, <i>Memb. of</i> <i>Council.</i>
The Masters of the City Companies.	Rev. F. D. Maurice.
Henry Cole, C.B., <i>Vice-</i> <i>Pres.</i>	The Lord Mayor.
Robt. Coningsby.	J. Stuart Mill, M.P.
Rt. Hon. W. Cowper, M.P.	Rev. Dr. Miller.
Sir Francis Crossley, Bart., M.P.	The Bishop of Oxford.
J. Bailey Denton, <i>Memb. of</i> <i>Council.</i>	J. Slaney Pakington, <i>Memb.</i> of Council.
Lord de l'Isle and Dudley, <i>Vice-Pres.</i>	Right Hon. Sir John S. Pakington, Bart., M.P., <i>Vice-Pres.</i>
The Duke of Devonshire.	Alderman Sir B. S. Phil- lips.
Charles Dickens.	Sir Thomas Phillips, Q.C., F.G.S., <i>Vice-Pres.</i> , <i>Chair-</i> <i>man of the Council.</i>
James Easton, <i>Memb. of</i> <i>Council.</i>	The Duke of Richmond.
C. W. Eborall.	Rev. W. Rogers.
Lord Ebury.	The Marquis of Salisbury, K.G., <i>Vice-Pres.</i>
Lord Elcho, M.P.	Titus Salt.
William Fairbairn, F.R.S.	Sir Francis Sandford, <i>Vice-</i> <i>Pres.</i>
Professor Fawcett, M.P.	Colonel Scott, R.E., <i>Memb.</i> of Council.
Peter Graham, <i>Memb. of</i> <i>Council.</i>	The Earl of Shaftesbury.
The Earl Granville, K.G., F.R.S., <i>Vice-Pres.</i>	Benjamin Shaw, <i>Memb. of</i> <i>Council.</i>
The Earl Grosvenor.	Sir J. P. Kay Shuttleworth, Bart., <i>Vice-Pres.</i>
Mr. Hansard.	S. Smiles.
G. W. Hastings.	Seymour Teulon, <i>Treasurer.</i>
Wm. Hawes, F.G.S., <i>Vice-</i> <i>Pres.</i>	Thomas Twining, <i>Vice-</i> <i>Pres.</i>
J. Pope Hennessy.	Alderman Waterlow, <i>Memb.</i> of Council.
Sir Rowland Hill, K.C.B.	E. W. Watkin, M.P.
Chandos Wren Hoskyns, <i>Vice-Pres.</i>	G. Watts.
T. Hughes, M.P.	George F. Wilson, F.R.S., <i>Memb. of Council.</i>
Blanchard Jerrold.	Vice-Chancellor Sir Wm. Page Wood, F.R.S., <i>Vice-</i> <i>Pres.</i>
Rev. C. Kingsley.	
Hon. A. F. Kinnaird, M.P.	
Lord Henry G. Lennox, M.P., <i>Vice-Pres.</i>	
The Bishop of London.	
The Sheriffs of London and Middlesex.	

The Council, on the recommendation of the
Committee, have passed the following mi-
nute:—

At the last and former International Exhibitions held
in this country, arrangements were made by the French
Government to facilitate the visits of skilled artizans,
and interesting reports on the exhibitions were made by
them to their government. Believing that such visits on
the part of skilled workmen to these great international
displays not only exercise a beneficial influence upon
the men themselves, but also upon the progress of in-
dustry in the country to which they belong, the Council
of the Society of Arts have resolved to raise a fund to be
employed in aiding a limited number of English work-
men to proceed to Paris for the purpose of studying the
present French Exhibition.

To carry this object into effect, they have agreed on
the following plan:—

1st. That a number of selected workmen (the number
to depend on the amount of funds at the disposal of the
Council) shall be assisted to proceed to and remain in
Paris a sufficient time (say three weeks), for the purpose
of making a careful study of the exhibition, and of such
factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return,
make a report to the Society of what he has observed
during his stay, in reference to the special industry in

which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

The following report has been made by the Secretary:—

To the Council of the Society for the Encouragement of Arts, Manufactures, and Commerce.

GENTLEMEN,—In compliance with the directions of the Council, I proceeded to Paris for the purpose of ascertaining what arrangements were likely to be available with regard to the lodging and boarding of such artisans as might visit Paris under the auspices of the Society.

I soon found, from inquiries made in various quarters, that little information of any value, as to the probable cost of private lodgings generally, or as to what lodgings would probably be available, was likely to be obtained; indeed, any figures or statements under this head at that time were not likely to be of any use, or in any way to be a guide to the deliberations of the Committee.

The prices asked at that time were exceptionally high, but there was every reason to believe that a reaction would take place, and that, after the exhibition had been open a short time, these prices would diminish.

Mr. Cook, the well-known excursionist, I found was prepared to contract for the lodging and boarding of 50 artisans per week, supplying two substantial meat meals per diem, for 6s. per head per day. I subsequently placed myself in communication with M. Le Play, the General Commissioner of the Exhibition, who informed me that a Special Commission had been formed, under a ministerial decree, for effecting the very objects I was in search of, and he gave me a special letter of introduction to the Chairman of that Commission, Mons. Devinck, formerly President of the Tribunal of Commerce for the Department of the Seine, and I had two interviews with that gentleman. It appears that the object of this Commission is to raise, by subscription or otherwise, funds for facilitating the visits to the exhibition of foremen, workmen, or labourers connected with industrial and agricultural pursuits, and for enabling them to study the exhibition in all its aspects.

The Commission proposes to raise a fund (to which the Emperor and Empress have subscribed largely) in order to provide lodging and board at a cheap rate for artisans, to assist workpeople in their travelling to and from Paris, and to supply gratuitously medical aid in case of sickness. Mons. Devinck informed me that the Commission expected to have under their control five thousand beds. These are situated in different parts of Paris and the outskirts. They have had placed at their disposal large buildings and barracks, and some of a temporary character have been specially erected in the neighbourhood of the exhibition, which will be furnished suitably for

the purpose, and beds will be arranged in the four and upwards in each room. In one of the buildings it is said that several hundred beds will be placed in one room.

Arrangements are made for breakfasts and dinner on a large scale and at a cheap rate, in a building set apart for the purpose, with access to the Champ de Mars, where 1,000 persons can take refreshments at one time.

These arrangements, more especially those for the workmen gratuitously in their travelling expenses, are intended for French workmen, but at the same time the organisation of the Commission is intended to be available for the workmen of other countries.

It is also intended that guides, speaking English and such other languages as may be necessary, shall be provided to conduct the men over such workshops as they may wish to visit. M. Devinck stated that concerning notice a sufficient time beforehand, the Commission would be prepared to provide lodging for such men as might be sent over and recommended to their attention by the Society of Arts, at a payment of one franc per night per head. Their breakfasts—a substantial meal of meat—and dinners would be obtainable in the building I have before named, at one franc per head for each meal.—I am, &c.,

P. LE NEVE FOSTER, Secretary.

P.S.—Since writing the above, I have received the following tariff of prices at the restaurant referred to in my letter:—

GRAND RESTAURANT OMNIBUS, PARC DE L'EXPOSITION (AVENUE LAMOTTE-PIQUET).

Prix des objets de consommation.

Pain	0fr. 10c.
Vin, le carafon	0 15
Bière, la chope	0 25
Bouillon	0 15
Potage	0 20
Bœuf	0 25
Légumes	0 20
Fromage	0 15
Café avec eau-de-vie	0 30
Roti avec légumes	0 40

On peut demander un seul des objets de consommation ci-dessus mentionnés.

Le consommateur, en apportant son pain, peut se procurer pour 0fr. 40c. l'ordinaire (bouillon et bœuf).

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

The Council have received offers of co-operation from a Committee for promoting cheap excursions to the Exhibition, formed under the auspices of the "Working Men's Club and Institute Union," and of which Mr. A. H. Laveré, M.P., is President, and Mr. Hodgson Pratt, Vice-President. This Committee has issued a notice to the effect that working-men may travel "to Paris and back, with one week's lodging," for 30s., or "with meat breakfast and superior bed accommodation," 44s. 6d. They estimate the total expense of stay (for one week), journey, and Exhibition ticket, at £3. Registration tickets, and every information relative to these excursions may be obtained from the Secretary, Mr. W. O. Pocklington, at 150, Strand, and at various Working Men's Clubs and Institutes.

HARVESTING OF CORN IN WET WEATHER.

The Council of the Society of Arts have resolved to offer the Gold Medal of the Society, and a Prize of Fifty Guineas, for the best Essay on the Harvesting of Corn in Wet Seasons.

The first part of such essay—after noticing the various systems at present adopted in damp climates for counteracting the effects of moisture upon cut corn in the field, and for avoiding such exposure in wet seasons by peculiar harvesting processes—should furnish a practical and analytic exposition of the best available means:—

- 1st. Whereby cut corn may be protected from rain in the field.
- 2nd. Whereby standing corn may, in wet seasons, be cut and carried, for drying by artificial process.
- 3rd. Whereby corn so harvested may be dried by means of ventilation, hot air, or other methods; with suggestions for the storage both in the ear and after threshing.
- 4th. Whereby corn, sprouted, or otherwise injured, by wet, may be best treated for grinding or feeding purposes.

The whole to be supplemented by a statement of practical results, and actual cost of each system described; and authenticated estimates of any process proposed for adoption, based upon existing but incomplete experiments.

The above requisitions are given suggestively; not to bind the writer to the order or to limit the treatment of the subject, provided it be kept within the scope of practical experience and utility.

The essays must be sent in to the Secretary of the Society of Arts on or before the 1st of January, 1868.

The Council reserve the power to withhold the whole or part of the prize, in the event of no essay being, in the opinion of the judges, of sufficient merit.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

A meeting of the Sub-Committee on Milk was held on Friday, the 29th March. Present—Lord de L'Isle in the chair: Mr. Harry Chester, Mr. Caird, Mr. C. S. Read, M.P., Mr. Ludford White, and Mr. J. C. Morton.

Mr. W. HORS, in reply to questions by the sub-committee, said that he was connected with the Dairy Reform Company, the chief depôt of which is at the West-end of London, and the intention was to establish branches in as many districts of London as possible for the sale to the public of pure unadulterated milk. At present there was only a private partnership, but it was called by the name of the Dairy Reform Company, in the first place to indicate its objects, and in the next place with a view to give it more extension hereafter. At present arrangements were made for the daily supply of milk

from about 300 cows, and the milk was brought to the establishment by road in the company's own vans, so that if possible there should be no tampering with it. They had already made arrangements for the sale of skim milk and a small quantity of new milk to the poor in Whitechapel. They had also a branch in Westminster, at which about twenty or thirty gallons of milk were sold per day. Upon the branch in Whitechapel being opened a dealer in that neighbourhood made an application to the company to make arrangements for the sale of the milk to him, instead of its being supplied through their own agent; but on inquiry being made into his character it was found that he was a person who would not be likely to carry out the objects of the company with regard to the quality of milk they wished to supply, and the application was refused. It was ascertained that he immediately afterwards went to the agent and offered him £20 to retire, and a little time after subscriptions were made by the dealers in that locality amounting to £100, which was offered to the man to induce him to retire from the agency of that branch. The agent however withstood the temptations of these offers, and the business of retailing new milk was continued amid many oppositions and annoyances on the part of the dealers. Those who dealt at the company's shop were subjected to personal interruption by a number of rough people employed to molest them. This having been put a stop to by the police, the opposition had placed some persons with a can of milk opposite the shop, and engaged men to "tout" the milk as that which the company really supplied, and many people discovered the imposition by the quality of the milk they thus obtained. He might say there was the most determined and organised opposition to the introduction of pure milk by the company into that quarter of the metropolis. The opposition parties reduced the price to a penny per pint by the addition of a certain quantity of water, and the agent was subjected to numerous remonstrances as to the quality of the article by the parents of children who had been sent by them to get milk at the branch, but who had been induced to buy that supplied by the competing parties. One of the principal—he believed the largest milk dealer at the West-end, came to the company in a very friendly spirit, and, with many professions of desire to put a stop to the "tricks of the trade," made various offers to buy milk of the trade. Among other offers was one to take 12 to 15 barn gallons of skim milk per day, stating that he had a contract to supply a workhouse with that quantity of new milk, and that the price at which the contracts for these establishments were let precluded the possibility of new milk being supplied unless it was well watered. The company had been applied to for tenders for various places, but on ascertaining the prices usually paid they refused, as it was impossible to supply pure milk on such terms. The prices varied from 1s. 4d. to 1s. 6d. and 1s. 8d. per "barn" gallon delivered. He believed the dealers received 17 pints as the barn gallon from some farmers. The company sold 16 pints to the barn gallon, this being the quantity which they received. The per-centage of waste in retailing 16 pints of milk in the small quantities usually sold to the customers by the milk carriers depended very much upon the carefulness of the milk-carriers in serving it out. In the company's shop he did not think the waste would be more than a quarter or half per cent. Most dealers did not profess to sell skim-milk, but they were ready to buy any quantity of it. The company had sold skim-milk at 1s. per barn gallon, or 1½d. per quart. As far as he had been able to ascertain, no new milk was sold in London except that which was supplied for the use of infants and invalids. He believed some dealers, if they got a good contract, did supply genuine milk, but the price they got would be equal to about 5d. per quart. The price of milk at the West-end at the present time had been reduced since the company supplied milk at 4d. per quart. As he passed a dairy in Brook-street that day, he saw the prices put up—New milk, 4d.;

skim-milk, 2d.; and cream 4s. per quart. With regard to the quality of milk sold generally in London, he took the existing evidence on that subject, chiefly that of Dr. Lethely and the statistics Mr. Morton had given, showing that the milk supply of London was derived from about 30,000 cows. Dr. Lethely stated, in his report to the Corporation of the City of London in 1864, that the addition of water to the milk amounted to about 30 or 40 per cent., and so if an Act were passed, rendering the use of water for the reduction of the quality of milk practically impossible, an increase of 50 per cent. in the number of cows from which the supply of milk to London was derived would be necessary to keep up the existing supply. Before the company's shop was opened they sold a large quantity of milk—about 70 barn-gallons per day, to a dealer at the East End. He bought it on the farm, and brought it away at his own expense, and he made his living out of it, although he stated he had a contract for a workhouse at 1s. 6d. per gallon, or 2d. less than he paid for it. The company made a tender for the supply of the Brompton Hospital at 1s. 3d. per imperial gallon, the milk being guaranteed to contain 12 per cent. of cream. That would be about 3½d. per quart. Milk varied very much in quality, even when not tampered with. Cows which had recently calved yielded richer milk than those which had calved five or six months; the milk of a young, vigorous cow was richer than that of an old animal. The best cows would yield considerably more than a pailful of milk at each milking, a pailful being about eight quarts. It was difficult to state what would be the percentage of cream from a bulk of milk taken from a number of cows of different ages and condition of circumstances, and it could only be done by a knowledge of the general average quality of the milk so mixed together, but the company had offered to guarantee 12 per cent. of cream in the milk they supplied. He could not say what was the average percentage of cream contained in London milk. It varied in different districts. The company had sent large quantities of skim milk to a charity in Soho-square, which was distributed to the poor gratuitously, and he had been assured that the skim-milk so sent was better than what the dealers charged 5d. per quart for. The quality of the milk of course depended very much upon the food of the animals. The company's supply was derived from a large dairy-farm near Barking. The cows there were fed on mangel-wurzel, hay, and grains. Some barley-meal was given to the cows which were heavy in milk, and those which were shrinking in milk were fattening. Mr. Hope further stated that dairy farmers could supply the dealers with milk wholesale at 2d. per quart delivered in London, but he thought there was very little delivered quite genuine at the stations. Many of the farmers no doubt adulterated their milk to a certain extent before they sent it away. He should say a large proportion of it was adulterated.

Mr. CAIRD remarked that where neither of these practices was resorted to, there was no produce which yielded so large a profit to the farmer as milk at 2d. per quart. He would, therefore, like to know how it was the company could not supply milk at less than double that price?

Mr. HOPE replied that the company paid 20d. instead of 16d. per gallon; that was the price paid to the Barking Farm Company. The carriage cost about 2½d. per barn gallon delivered at the depot.

Mr. LUDFORD WHITE asked what profit Mr. Hope thought the retailer ought to have per gallon to pay him for his trouble.

Mr. HOPE thought that a small dealer required a margin of profit of 1s. per barn gallon, or 6d. per imperial gallon, to pay for the transit from the station and the delivery in town, to cover waste, wear and tear, and wages. The quantity of milk taken by each customer was small, and the labour of retailing it was great. The experience of the company had as yet been short, but as

far as it went he should say that no milk-carrier could retail more than 80 quarts in the two deliveries per day. That depended, of course, upon the number of separate deliveries and the distance between the customers. Sixty quarts per day, he thought, would be as much as some carriers could deliver on an average.

Mr. CAIRD remarked that the question was, whether if milk could be produced to yield a good profit to the farmer at 2d. per quart, it could not be sold by the dealers at less than double that price, and give a fair margin of profit to them?

Mr. HOPE said the whole question turned upon the purity of the article supplied. He thought the reason why there was not a greater demand for milk in London was because people felt that they could not get genuine, and therefore used as little of it as possible, and though the dealers got it at prices from 1s. 2d. to 1s. 4d. and 1s. 6d. per gallon, until lately they had been charging 5d. per quart for what they called real milk.

Mr. CHESTER inquired what security the company had that the milk they sold to dealers, and that which was distributed by their own carriers, was not tampered with before it got to the consumers?

Mr. HOPE said of course, in the case of dealers the action of the company ceased upon the delivery of the genuine milk to them; but in the case of their own carriers the cans were sealed at the top before they were sent out, and if the customers saw the milk done by the man they could ensure having the genuine article at their own doors. Adulteration by water could be detected by the lactometer.

The CHAIRMAN suggested that cream, from its great price, offered greater temptation to adulteration than milk.

Mr. HOPE replied, that the dealers "protected" themselves in another way, namely, by the measure given. When the company was organised he went to the person who made the small delivery cans for the private dealers in London, to order some dozens of cans; and in speaking of those which were wanted for cream he said "Do you want them 'full'?" which he found meant whether he required them to be of full measurement. He then learnt it was the "custom of the trade" to have cans for cream which held twenty-five per cent. less than the proper measure. A large West-end dealer offered to purchase the cream of the company at 3s. 6d. per quart, which he sold at 5s. and 6s. per quart. In course of conversation he (Mr. Hope) asked him if he gave the full measure in cream; to which he replied, "Oh, yes; that is to say we give full 'cream' measure," and implied that was as much understood by the public in the article of cream as the wine-merchant's bottles to the gallon of wine. A small measure was thus adopted for the more valuable commodity of cream. It was, no doubt, a more difficult operation to adulterate cream than milk, but he believed the dealers were generally "protected" themselves by the short measure. The public got a genuine article, but 25 per cent. short of the measure. The dealers bought the cream full measure, by the imperial quart or gallon. When asked why he preferred to pay 20d. per gallon for the milk from this farm instead of 1s. 4d. for that delivered at the railway stations, the reply of one dealer was "There is a great deal more 'room' in it;" which led him to infer that the farmers sent out their milk adulterated to a certain extent. He had seen a great deal of tampering with milk at the railway stations on the part of porters. He had seen them tipping the cans over and filling jugs from them.

Mr. READ suggested that it was the practice of some dairy farmers to give food to cows with a view to the quantity rather than the quality of the milk they produced.

Mr. HOPE hardly thought that course would be adopted by an intelligent farmer. Milch cows required the best food to keep them in constant milk. Grains tended to

crease the quantity of milk but did not improve the quality of it, and required a corrective.

Mr. CHESTER asked if it was part of the plan of the company alluded to to open branches in other parts of London?

Mr. HOPS replied that they hoped to do so eventually every part of London if possible, and he had no doubt 4d. per gallon would be the price at which the company would be able to sell their milk. He believed the company or their tenants would make an ample profit at that price, and he had no doubt, as the prices of the milk company were diminished, and as their business increased, they would be able to reduce their margin of profit from 1½d. to ½d. or ¾d. per quart. Mr. HOPS then proceeded to explain the plan which had been adapted by the company for collecting the cream from the surplus milk, and also their experience in making butter from the new milk on their own premises. As far as the experiment had gone at present, using the atmospheric churn, the yield of butter had been as much as an average of 1½lbs of a pound of butter from two imperial gallons of milk. That was no doubt in excess of the yield of ordinary new milk. There was some difficulty in the use of the atmospheric churn, from the extreme nicety to which it was necessary to regulate the temperature of the churn. The best yield of butter was at 68°. If it were raised above that, such butter as was produced was of a lardy appearance and a colour which made it unsaleable, and the quality was not good. There was sometimes difficulty in getting the precise temperature required. The residue under the operation of the atmospheric churn was nothing but re skim milk, perfectly sweet. It was not what is usually termed buttermilk. The butter, when produced in sufficiently large quantities, was sold in Newgate-market at 1s. 6d. per lb.; and none but very freshly made butter was sold in the company's shop at 22d. per lb. at the present time. He had not found that any prejudicial effect was produced on the milk by the carriage from the farm to the establishment in London so far as churning qualities were concerned. As the result of the consideration of the subject, and looking to the natural laws by which the process of the rising of the cream upon the surface of the milk was governed, he had tried the experiment of "setting" the milk in deep and narrow metallic cylinders, instead of the ordinary method of doing so in wide and shallow vessels. The result was that in the long and narrow cylinders the cream rose more quickly than was the case in the shallow vessels, and, forming a compact mass at the top, it could be dipped out with much less labour and in much less time than was required to skim the same quantity of cream off the surface of the shallow vessels, and there was a less quantity of surface cream left upon the milk. Where there was a large quantity of milk to be "raised," and when the shallow vessels were used for the purpose, occupied two women the whole of the day in skimming off the cream, whereas by the use of the deep cylinders the cream was removed by dipping out the mass which formed to a considerable depth at the top of the cylinder. The results of the latter method of raising the cream were tested in the first instance in a glass tube about 16 inches high and two inches diameter. This tube was filled with new milk in order to see whether his assumptions were based on fact. The milk was placed in the tube at half-past nine o'clock in the morning, and at five minutes past 11 nearly the whole of the cream had risen. His partner, who was at first sceptical on the point, afterwards admitted that the theory was proved to be correct. That plan he believed would in future be acted upon in the establishment, and his endeavour would be directed to obtaining large glass cylinders, five or six feet in height and nine inches diameter, in which to raise the cream in the manner he had described. By the use of glass cylinders the line of demarcation between the two liquids could be exactly ascertained, and the removal of the cream be conducted accordingly. The wasting sur-

face of cream by this method was nothing in comparison to that which would exist in the nine or ten shallow dishes that would be required for raising the same quantity of milk as was contained in a cylinder of the dimensions he proposed to adopt. Temperature had much to do with the rapid rising or otherwise of the cream. The company had painful experience of that during the recent very severe weather. The cream would not rise, and the milk had to be sold, or rather given away, to the company's loss.

Mr. CAIRD mentioned that when travelling in Sweden in the summer time, he was much struck by the practice which was adopted by a large and thoroughly experienced dairy farmer, of placing the vessels containing the milk from which the cream was to be raised, in water cooled by pieces of ice being placed in them. The reason given for this was that it caused the more rapid rising of the cream; that was a plan adopted by a man of great intelligence and practice; and, therefore, he concluded it was based on sound conclusions, although differing from his preconceived ideas on the subject.

Mr. HOPS suggested that the satisfactory results mentioned by Mr. CAIRD might have ensued from the depth of the vessels in which the milk was contained, rather than the icing of the water in which they stood.

Mr. CAIRD said it was not so, because careful experiments were made without the ice, and the results were not so satisfactory. It was found that the ice had the effect of hastening the separation of the cream. This practice was adopted in a dairy of 300 cows. The little wells of water in which the vessels were placed were a very simple affair, and the whole thing did not involve any great expenditure of money.

[The French milk can which had been sent to the Committee from Paddington Station having been exhibited to Mr. HOPS, that gentleman expressed his unqualified approbation of it, both as regards its handy size and the material of which it was constructed, as also the mode in which the top was fitted in, so as to prevent the agitation of the milk in travelling by railway or other conveyance.]

Mr. BROOKS, an officer of the London and North-Western Railway Company, having been introduced to the sub-committee,

The SECRETARY read a return of the gross quantity of milk carried on the above railway, which had been furnished from that company, as follows:—

	No. of gallons.
1. Milk brought to the Euston-square terminus in the year ending December, 1866.	490,320
Ditto in year ending December, 1866 ..	1,209,284

2. The stations from which the milk arrives at the Euston terminus are the following, viz., Aylesbury, Bletchley, Cheddington, Claydon, Crick, Dunstable, Leighton, Marston Gate, Newport Pagnell, Northampton, Rugby, Swanbourne, Tring, Ullenhurst, Winslow, and Wolverton. N.B.—The quantities received from each station cannot be arrived at with any degree of accuracy, from the mode of keeping the accounts not being framed with such an object in view.

3. The company run one special train with milk from the country daily, and return the empty cans in like manner.

4. The milk is conveyed [in cans provided by the senders] on open carriage trucks, and no special mode of stowage is resorted to.

Mr. BROOKS said, in reference to the figures just read, there was a considerable falling off in the quantity of milk carried since the period embraced in this return. He had taken out the last week's cash receipts for carriage of milk, and he found they were only £83, or equal to about £4,300 a-year, as compared with the corresponding period in 1866, when it was £229, or equal to about £12,000 a-year. He accounted for this decrease by stating that the London milk trade was regaining its normal con-

dition previous to the cattle disease breaking out. The same rates were charged this year as last. The charge for a distance not exceeding 100 miles was 1½d. per gallon, and exceeding 100 miles 2d. per gallon (imperial). When the great increase in the traffic commenced, milk was sent up from places 180 and 200 miles distant—from Huddersfield, Macclesfield, &c. The greatest distance from which milk was sent now was about 95 miles. The largest quantity of butter sent from any place on the London and North-Western line was from Aylesbury, but that did not come under his attention, as the carriage of that article was by goods trains. He did not think any material improvement could be made in the carriages which were used for the conveyance of the milk, carriage trucks being now used for that purpose. Those now used were about as well constructed in respect of the springs as they could be, and it was desirable that the milk should be as little shaken on the journey as possible. He thought the size and form of the French milk can much better than that in use in this country. He considered it an advantage that the milk should be fixed as solidly as possible in the cans, but he had heard no complaints as to the condition of the milk being deteriorated by the journey on the railway, although he thought it might be somewhat affected in hot weather; but that, he believed, depended a good deal on the quality of the milk and the distance travelled.

Mr. MORRIS (being appealed to on this point) said the London-produced milk sold at a higher price than that which was sent from the country, the highest price paid by the dealers being for the milk which they themselves milked.

Mr. Brooks said the French can was much more convenient to handle at the station. It was a stipulation with the dealers that their men should assist the porters in unloading the cans, because the cans were too heavy to be handled by one person. The weight of a can filled with milk would be near upon 200 lbs. The trade came to be of such an extent as to lead to the putting on of special trains for the purpose. They were timed as passenger trains, and passengers could travel by them if they pleased. The milk was brought to the various stations in time for the arrival of the milk trains. One train arrived in London at a quarter to twelve in the forenoon: that was for the afternoon supply; and the second train arrived about half-past eight in the evening: that was for the next morning's supply. The reason for putting on the special milk train was owing to the impediment to the ordinary passenger trains caused by stopping at the stations to take up the milk. With regard to improvements in the method of carrying milk and cream long distances, Mr. Brooks mentioned that, during the time of the greatest scarcity of milk, an arrangement was made for bringing cream from a distance as remote as Carlisle, and that was done by the article being placed in small cans—much smaller than the French milk can—and carried suspended in the truck; but, when it arrived in London, it was found that the cream was reduced almost to the consistency of milk. That trade was therefore abandoned. He believed in that case the vessels were filled as full as possible, to prevent the shaking of the cream. In the long journey of 300 miles the cream was converted—by some means he could not account for—into the consistency of milk. It arrived in London quite sweet, but could not be used as cream. There was at the present time a considerably larger quantity of milk sent up by the railway than was the case previously to the cattle plague, and he thought it likely that the present quantity would be continued for some time. The quantity began to fall off in March and April last year, from 161,000 gallons in March, to 142,000 gallons in April, and from 125,000 gallons in May, to 95,000 galls. in June; in July to 80,000 galls., in August to 64,000 galls., in September to 63,000 galls., in October to 63,000 galls., in November it fell

again to 59,000, and in December it rose to 66,000 galls. The quantities for the corresponding months in 1866 were—July, 6,288 galls.; August, 17,400 galls.; September, 61,888 galls.; October, 95,484 galls.; November, 116,760 galls.; and December, 148,296 galls. Thus it would be seen that the marked increase in the milk trade on this line commenced in the month of August, 1865.

Mr. CAIRD remarked that was the month in which the disease first broke out in the herds of Lord Grafton and Miss Coutts.

Mr. Brooks, in reply to other questions, stated that other means were taken by the railway company to develop the milk trade than the putting on of milk trucks and eventually establishing special trains for it. The rate charged was increased as soon as the special trains were put on, and that had not had the effect of diminishing the quantity. The rates were increased from a penny per gallon under 100 miles to a penny half penny, and that rule was still continued for that distance. The trade at present amounted to about 54,000 gallons per month. Those parties who made complaint about the increase in the rates would not have calculated at what price per ton the company carried the milk, or they would have found that the milk, including the weight of the cans, was carried up to a distance of 100 miles for 1s. per ton. When the milk train arrived the dealers assisted in the unloading of the vans, and the milk was carried away in the dealers' own conveyances. He was not aware of any other means by which the milk could be more promptly or more rapidly distributed than it was under the present system. When the large business in milk was commenced the dealers wanted something of a market place, but there was not space enough at the station for that; they then adjourned to some of the adjoining streets, but that was stopped by the police authorities. As far as the railway authorities were concerned, he imagined it made no difference to them whether the smaller sized can were used or the present large size, inasmuch as the same quantity would have to be carried, whether it were done in large or small cans. Undoubtedly the French can was more conveniently handled, and a man of ordinary strength could load or unload one of these cans without help. He apprehended if the small cans were adopted, waggons with two tiers something in the form of the sheep vans, would answer the purpose, as it was not desirable to place the load too high, but if special vehicles were constructed, they must be reserved for the milk traffic alone, and would not, like the carriage trucks now in use, be available for other purposes. There had been cases in which cans of milk had been stolen from the station by the milk dealers; and he knew of one instance in which the offence was condoned by a public apology and the payment of a sum of money to the poor-box of the police court.

NINETEENTH ORDINARY MEETING.

Wednesday, April 24th, 1867; C. W. SIEMENS, Esq., F.R.S., in the Chair.

The following candidates were proposed for election as members of the Society:—

Ainalie, Montague, Grizedale, Hawkhead, Windermer.
Amhurst, W. Amhurst T., Didlington-hall, Brandon,
Norfolk.

Essell, George, The Precincts, Rochester.
Fisher, Thomas, 24, Hanway-street, W.
Hutton, Thomas Winder, 5 and 6, Newgate-street, E.C.
Maddick, Alfred, 40, Clarges-street, Piccadilly, W.
Rylands, Peter, Bewsey-house, Warrington.
Sayer, Commander George, R.N., Statenborough-house,
Sandwich.
Tinne, John A., F.R.G.S., Briarley, Aigburth, near
Liverpool.

Toler, Hon. Ottway Fortisquae, 6, Albemarle-street, W.
Weld-Blundell, T., Ince-Blundell-hall, Great Crosby,
Liverpool.

The following candidates were balloted for,
and duly elected members of the Society :—

Brown, Thomas P., 24, Surrey-street, Strand, W.C.
Despointes, F., 11, St. Luke's-road, Westbourne-park, W.
Jones, Sir Willoughby, Bart., Cranmer-hall, Fakenham.
Roe, Charles Wm., Padmore-villa, Sunny-bank, South
Norwood, S., and 37, Moorgate-street, E.C.

The Paper read was—

ON THE CONSTRUCTION OF IRON SHIPS, AND THEIR PRESERVATION FROM CORROSION AND FOULING BY ZINC SHEATHING.

By S. J. MACKIE, Esq.

In view of the magnificent total of British iron ships, I need not apologise for taking a survey of the state in which they are kept, and the manner in which they are built, in order to show that they are neither built nor kept as they ought to be, if I can succeed in proving that iron ships might be better built and better kept than ever they have been. Still more shall I be justified in calling attention to these subjects if I can further show that the present depression in the iron ship-building trade may undoubtedly be released, and double the amount of tonnage of ships annually constructed hopefully expected for the future of the iron ship builders.

For my own part, I am the more free to speak boldly and unreservedly, in that I am not about to advocate any plan of my own for the remedy of the evils that exist. To my mind there is but one right way of doing everything that has to be done. Men did not build ships when they first began to navigate the seas, but scooped out into canoes the trunks of trees, such as had served them for sitting astride to cross the rivers in their way. Nor did they, when wanting vessels of burthen to carry interchangeable commodities for longer distances, build wooden vessels as large as the East Indiamen of the last century, or as swift as the American clipper of this. So iron ship-building, although a modern invention, did not start into existence in perfection, but has gone through various modifications and improvements, until it arrived at its present eminent condition. Progress has still to be made. Far be it from me, however, to deny, or to attempt to diminish the ability and the perseverance of the eminent engineers and practical thinkers who have foreseen and avoided so many difficulties, and have encountered and conquered so many more, nor to undervalue the experience and skill of constructors and skilful workmen. Nor can it be my wish in any way to detract from the deservedly high fame which the English and Scotch iron ship building yards have so far maintained. But there may be a time in the history of iron ship building, as there has been in most other great branches of manufacture and commerce, when those who have got a long way towards perfection become enamoured of what they have done, and think nothing better to be possible. Such is, to a regrettable degree, the present condition of iron ship builders. Having done a great deal, there is no disposition to go a step further, although it be but one step further that is required, to make modern ship-building as perfect as, in the present condition of science, is possible. The corrosion and fouling of ships may be said to be no business of the ship-builder; and most men engaged in the trade might possibly admit that cleaning, repairing, docking, and tinkering constitute a very large proportion of the ship-builder's business. But herein lies a serious error. Shipowners and merchants are undoubtedly more closely concerned in the preservation of the ship, and in her cleanliness and speed at sea; but if the capacity of keeping a clean hull would create an additional demand for

iron ships, is not the means of effectually preventing the fouling of an iron hull in salt water well worthy the attention of the iron shipbuilder?

Such a means exists, and has been proved undeniably by experiments, and yet there is no disposition to give it practical adoption; a fearful evil exists in the un-mechanical butt-joint, and yet iron shipbuilders go on planing, and caulking, and fitting at enormous cost, and boast of the beautiful work that sends every iron ship afloat to sea, with the most effectual device for her destruction which the highest scientific knowledge and the most practical ingenuity could conceive. If our commercial shipbuilders will not take the lead, we cannot wonder that the artificers in our naval dockyards are still permitted to pride themselves on the fallacious finish of their butt-joints; and while shipowners spend thousands of pounds in docking and cleaning their ships, allow corrosion and decay to have unlimited rule, and besmear the hulls of vessels worth tens of thousands of pounds with red lead, phosphorus, arsenic, and other ineffectual poisons, we cannot express much surprise that to the complaints of naval officers of the fouling and corrosion of their ships, the incasing of our gigantic iron-clads in outer wooden copper-sheathed skins should be the expensive relief afforded by the Admiralty, and that Hay's composition and other so-called anticorrosive and antifouling paints should be in official favour.

There is but one way of effectually preserving iron ships, which is by sheathing them with zinc in the same way as formerly wooden vessels were sheathed with copper, and as the plan proposed for attaching the zinc plates to the hull has elicited a perfect means of getting rid of the insecure butt-joints in the construction of the vessel, as well as rendering it easy to make the skin of the ship flush and fair from top to bottom, and end to end. I have for these reasons proposed to consider the practical construction of iron ships in connection with the main object of this paper, namely, the prevention of the iron hull from corrosion and fouling, by an external sheathing of zinc plates.

No one of even the slightest experience of iron ships can fail to be aware of the extent of the corrosion and fouling to which they are liable. But of what takes place ordinarily, no notice finds its way into the columns of the newspapers; and it is only of exceptional cases, where size makes the particular vessel remarkable, such as in the case of the *Great Eastern*, or where the matter commands attention on account of its national importance, as in the case of some of our formidable iron-clads, that any reports come before the general public. The matters of corrosion and fouling are not, however, the less serious that they are permitted to proceed unhindered and on a most gigantic scale in silence.

We have first to do with corrosion. The corrosion to which iron ships are subjected is the oxydation of the metal. Wooden ships were liable to perforation by sea-worms, and to fouling by sea-weeds and barnacles. After a time it was found that copper attached to a wooden ship's bottom would keep perfectly bright and clean. The use of copper sheathing was first adopted by the Admiralty in 1761, under the prevailing idea that its poisonous influence would be obnoxious to marine vegetation and life, and when H.M.S. *Alarm* was found clean after a four years' voyage, the success was attributed solely to its poisonous character. The reign of copper at the Admiralty has lasted from that date to the present hour. But copper dare not be put on an iron hull. What was bad before in the extent of the corrosion becomes infinitely worse under the influence of the galvanic action set up by the contact of these two metals.

In the early days of the sheathing of wooden ships it was found that iron bolts in the timbers, and other objects of that metal in contact with the copper, were eaten away incredibly quickly; and in various accidental ways injuries of a like and very serious nature have repeatedly happened from the contact of copper with the

hulls of iron ships. Indeed, it is admitted upon all hands that copper sheathing cannot be applied to iron ships, and that if it were, the total destruction of the hull would be accomplished at the most rapid rate; nevertheless, as copper prevented the fouling of wooden ships, there has been from the commencement of the era of iron ship-building a too general and very fallacious hankering for some method of covering iron ships with copper. Various compositions of india-rubber, felt, and other insulating materials have been interposed, in various cases, between the copper and the iron skins of certain vessels; and even at this moment under the persistent tradition of the *Alarm*, or the commercial influence of Muntz's metal in official quarters, the Admiralty are having some of our huge and costly iron-clads entirely coated below the water-line with a jacket of timber several inches in thickness, in order to insulate that copper sheathing which the wise men of a century since very properly adopted for the preservation of the ships of their day, but which it is surely inexcusable for the men in high places now to put at a dangerous risk upon the hulls of the most costly vessels ever sent upon the seas, when another and cheaper metal, bearing exactly similar relations to the iron which copper did to the wood, could be more simply and more easily applied. It is not possible to ensure the insulation of the copper sheathing from the iron hull of a vessel afloat. Even admitting that the insulation can be perfected when the ship is sent out of dock, the many casualties she is subjected to on her voyage are constantly tending to injure and destroy the insulation. Grazes and rubbings against piers and quays are always liable to make holes in and to strip off portions of the sheathing, whilst plates of the covering metal may be peeled in various ways upon the open sea, and, once contact permitted, nature will not be slow in putting galvanic currents destructively in action. Even when an iron ship is actually encased in double planking, the shrinkage of the wood or the opening of the joints by strains of the vessel's motion by permitting the percolation of sea-water will give a connection between the two dissimilar metals of the hull and the sheathing, and the iron of the armour and skin will yield not the less quickly, not the less certainly, not the less dangerously, that it is hidden from the eye-sight, or be the less expensive or difficult to repair, that several inches thick of timber have to be removed from the exterior of the ship before the extent of the injuries can be ascertained. One example of the effect of copper on an iron ship is as sufficient for practical illustration as a thousand, if there be a thousand similar facts existent to back it up; and if facts upon this point be desired there would be no risk in engaging to produce a volume. We take one of three years since, that comes readiest to hand. It is from *The Hereford Times*, of 14th November, 1863. Truth is often spoken of as deep in a well, and rare fragments of honest truth are often to be culled from provincial newspapers:—

"Here is the last little piece of news from the iron squadron:—As lately as May in the present year there lay at her moorings off Folly Point, in the Medway, the youngest of these Titans—the *Royal Oak*. Of enormous tonnage, giant proportions, and hull that seemed to make the tired ocean groan under her, she was pointed out with pride by yachtsmen and passengers as a brand-new 'bulwark of England.' Towards the close of May she got under weigh a maiden ship, 'ataunto,' 'spick and span,' as handsome as paint and varnish could make her, to join the Channel fleet in its cruise round England. She turned out a capital sea-boat; she showed her heels to the best of the squadron before the wind; and more than once had to lower her topsails to let the laggards in her wake overhaul her. She was 'another success,' and the Admiralty were as proud of her as the people. Now she comes into port, and what do we hear? That smooth and burnished bottom, coated with 'Muntz's metal'—thanks to which she made such fine sailing—has put her

hors de combat far sooner than fighting could have done. This ship—this Admiralty pet—which has been just months in commission, is as rotten already as a ship after forty seasons. They have got her into dock, and they find that all along the line between her skin and her lower plating, the great and costly iron plates have perished into something like plumbago. There are holes three-quarters of an inch deep, in just that part of her armour which protects the 'wind and war line.' Where the hooks of the side-ladder have held the sea-water and the sheathing to do their work, the iron is gone in a deep furrow, and from all the joints of the submerged plates there oozes a black slimy liquor which is doubtless chloride of iron, and which means that plate and rivet and backing are rotting altogether, inside and out of sight. Into some of the four-and-half inch plates, which were to guard this treasure vessel, you may poke a pen-knife blade half way to the handle, in spite of an ingenious band of some sort of metal, not intelligible to those who made the discovery we are describing, the effect of which was to destroy galvanic action. In a word, as we have said, the maiden monster has come into dock rotten from her first trip.

This is the account of the effects of copper sheathing three years ago, and yet during the present spring the costly *Northumberland* has sailed from Chatham for Devonport to be covered with the same destructive metal, and the huge ship, whose launch was a ruin to a labour, may come perhaps, after a brief life of rapid consumption, to an inglorious if not cataclysmal end. How, it will be properly asked, is it proposed to overcome this evil. The corrosion of iron ships may be effectively stayed by the use of zinc sheathing. The zinc sheathing may be put direct upon the iron skin, and the iron will not only not be injured, but it will be preserved. The idea which has been practically worked out by Mr. Daft, in his well-considered plan of zinc sheathing is this:—If the galvanic action set up in the cell formed by the iron ship and the covering of sheet copper—or Muntz's metal, which is a compound of copper—be destructive of the iron of the vessel, then its use, as a means of preservation, that metal to which we will stand in the voltaic circuit, as the copper is in the former case did to the iron. In other words, if the ship and her sheathing form a voltaic battery, the elements of which stand in such electro-chemical relation to each other that the ship shall be destroyed, then to find the way to reverse the conditions of that battery, so that the ship shall be preserved. This is done by the substitution of the element zinc for the element copper.

That we may not appear to be pinning our faith upon Mr. Daft's intellectual sleeve, we will quote a few passages from Mr. Lamport's paper, "On Wood and Iron Ships," in Vol. IV. of the *Transactions of the Institute of Naval Architects*. He proceeds thus:—

"First.—When chemical decomposition is produced upon two metals in contact, the more oxidisable becomes electro-positive, and the less oxidisable becomes electro-negative. The various metals in common use may be arranged in a series, in which those first in order become positive by contact with all those that follow, and negative with those that precede—as zinc, iron, lead, tin, copper, silver, gold, platinum.

"Secondly.—When any two of the above metals are combined in a fluid capable of acting upon one of them by chemical decomposition, a galvanic current is produced, passing from the more to the less positive metal, which then becomes negative. The energy of the current is in proportion to the vitality of the chemical action, which is confined to the metal which is most electro-positive. The other, becoming negative, is protected from the chemical action. For example, if iron and copper be combined in an acid or in sea water, iron being more electro-positive than copper, is chemically decomposed, or, to use a more common phrase, is 'corroded.' The galvanic current, passing from the iron at

generating metal to the copper as the receiving metal, changes the condition of the latter from a naturally electro-positive condition to one relatively negative. The metal, thus rendered electro-negative by the galvanic current, becomes proof against the action of the fluid as a chemical agent. No decomposition takes place, and it assumes the condition of a 'protected' metal, while the more positive one is still more rapidly eaten into and decomposed by the stimulated chemical action. If in place of copper and iron we take iron and zinc, the same process takes place, *reversed*, however, as regards the iron. Zinc, being more positive, is chemically decomposed, and the current passing to the iron renders it negative, and, consequently, insoluble or 'protected.' It will, therefore, be observed that it is the chemical action that is deleterious, and that the ensuing galvanic current, by changing the natural condition of the least positive of the metals to that of a negative receiver, protects it from the chemical decomposition to which alone it would have been subjected. Further, the union of three or more metals produces similar results—as with copper, iron, and zinc. The corrosion takes place in the most electro-positive, zinc, to the protection of the other two.

"Thirdly.—To produce these phenomena actual contact is not necessary, as the fluid itself becomes a medium of combination.

"Fourthly.—The relative size of the positive and negative metals has no influence upon the direction of the current, which passes always from the most electro-positive metal to the other, irrespective of surface or mass. A small piece of metal, therefore, may absolutely protect a far larger mass of one rendered electro-negative. A considerable preservative effect has been observed when the surface of zinc has been to that of copper as 1 to 1,000."

The relationship of zinc to iron in a galvanic cell is undoubted: indeed it may be and was proved by the first voltaic battery recorded, namely, that formed by simply placing two plates of the metals, with their lower edges touching like a V, in a glass of salt and water, or diluted sulphuric acid. This experiment may be performed by any one with pieces of zinc and iron and copper and iron respectively coupled in two ordinary tumblers filled with salt and water. The solution in the one will be colourless, that in the other quickly stained of a deep blood-red hue with the oxide of iron, which will be also deposited in quantity at the bottom of the glass in the condition of ochre. The iron in the other cell will keep for weeks and months perfectly unattacked, whilst the zinc in connection with it will remain bright and clean, from gradually and continually losing a small portion of its volume, a very slight quantity of the white oxide of zinc being deposited in the tumbler.

Zinc sheathing applied to wooden vessels does not answer; for when zinc is isolated on wood it becomes its own protector. The zinc oxidizes and the hard oxide which results soon covers the surface, and exfoliates so slowly, and irregularly, that fouling takes place to a considerable extent. Copper, on the contrary, when thus isolated on wood, suffers sufficient chemical degradation to present a constantly clean surface. What the zinc requires to compete with the copper for brightness and cleanliness is a little stimulus; and this accelerated action is effectively provided for by the galvanic current set up by its contact with iron. Thus the one thing needed to make zinc sheathing a success is involved in that desideratum so long necessary for iron ships—the prevention of their corrosion and fouling by the direct application of a metal sheathing. If the expensive sheathing with copper be so repeatedly and persistently attempted, the greater cheapness of zinc cannot be any valid objection to that metal—and this corrosion and fouling can be prevented by zinc sheathing, and that, too, with the additional vital advantage that it will at the same time insure the most perfect preservation of the

ship. We have in zinc exactly what is required—a metal that may be put direct, without any insulating material whatever, upon the bare surface of the iron skin of the ship—that when so placed will form a voltaic cell, the electro-chemical action of which will preserve the iron, while the zinc will only sufficiently and regularly degrade and exfoliate to maintain a clean surface in any waters, at the same time that it is capable of enduring for four or five years without removal.

I come now to the second point—fouling. This, like corrosion, or dangerous defects of construction, is not the less serious and expensive that it is kept out of the arena of general discussion. It is not to the advantage of ship-owners to make any fuss about what they know not how to prevent, or to mention any scheme which has any probability of doing that which they think will seriously diminish, if not entirely ruin their business. The fouling of government ships, too, not only involves loss of speed, but more steam-fuel, more food and provisions, longer pay for the crews, and expensive docking and repairs, necessitating the labours of hundreds of men, often for considerable periods of time. I myself saw, a few months since, at one of our principal naval yards, employed for the best part of a day upon one of our large iron-clads, in bringing her into dock and shoring her in position, upwards of 800 men. But as nobody but the public has to pay the expenses of fouling, and bringing grist as it does to the official mill, it is not at all likely to receive correction so long as that bountiful paymaster—the nation—takes no heed whatever of the matter.

That the fouling of iron ships is a most serious detriment and a continual exorbitant expense, the very fact that copper sheathing is so persistently attempted, in spite of all obstacles and dangers, is collateral evidence of the very strongest kind; and, indeed, no shipowner or captain of any experience, if put to the test of his veracity, could deny it, however unwilling he might be, from what he probably, but very erroneously, would consider prudential motives, to admit the truth of the assertion. On this point, however, as on others, I intend to take evidence, and from the abundance of witnesses I will now select to bring Mr. Lamport into court. In Vol. IX. of the "Transactions of Naval Architects" he admits that the cost of copper is not the reason why iron ships are not sheathed with that metal. At page 289 he says:—

"The next section takes in the doubtful qualities of iron, and the first is that of superior economy of maintenance and repair. I admit that iron ships do not incur the periodical cost of coppering. But why? Certainly not because the outlay is not needed, but because owners are compelled to forego its admitted advantages. Chemical action forbids the contact of copper or yellow metal sheathing with iron; but I put it to any owner of an iron ship whether he would not willingly pay the cost of coppering to avoid the drawbacks of fouling. If so, can the constrained saving be considered in the light of a gain? Its result is a foul bottom and a lengthened and uncertain voyage; and, as time is money, such saving is anything but economy. But is there no counterbalancing outlay from scraping, painting, or otherwise coating iron ships' bottoms, and is there no loss of material from oxidation of the iron itself to set against the caulking and coppering of wooden ships?"

"By Lloyd's rules, the thickness of the plates for twelve years' iron ships is $\frac{3}{4}$ -inch more than those of the six years' grade. The experience of the committee, therefore, points to $\frac{3}{4}$ -inch as the waste due to six years' wear and tear. In six years, a twelve years' vessel will be liable to be reduced, we may suppose, to the condition of a six years' ship, and a six years' vessel in this period may be supposed to be reduced to a condition to which no class whatever would be assigned. Making every allowance for excess of caution, enough remains to show that the annual depreciation of the iron plates is considerable; and this, added to the cost of frequent dock-

ing, scraping, and painting, cannot leave much difference between the annual expense of maintenance of wood and iron ships."

Neither is the additional cost of steam-power required to produce an inferior degree of speed in the ship by any means a trifling consideration when the class of the vessel is one of large dimensions and horse-power. Upon this point I will put another reliable witness into the box, again making the selection from the Institute of Naval Architects. At the meeting of 28th February, 1861, Admiral Halsted spoke these words:—"Now I come to another terrible business, and one in which I hope my colleagues in this institution will take a leading part. Here is the *Warrior*, with her 1,250 nominal horse-power engines, to go 14 knots an hour. But pray for how long? How many weeks will elapse at sea before the fouling of her bottom will reduce her 14 knots to 12, and even below that? As everybody here knows, perhaps better than myself, the fouling of the bottom of iron ships is a question connected, and closely connected, with the nature of the material itself; but I think it is not generally understood that it is not a mere question of the difficulty of preventing the corrosion of the bottoms of iron ships. There are a dozen ways by which actual corrosion of the metal may be prevented, but the misfortune is that all these appliances have the effect of presenting such an enticing surface to marine substances and animals that they carry on their little operations till there is no end of them, and in six months the surface of the bottom of your ship is destroyed, in a great measure, for all purposes of speed. It is wonderful, the money which has been paid away in this country on that account. We possess some 600 iron screw ships, and there is not one of them but is subjected to this difficulty at least twice a year. And it is not the mere expense of hauling into dock, cleaning the bottom, and re-painting; but it is the number of steam horses that have to be fed to their fullest extent constantly, although the effect produced by their efforts is gradually diminishing. Neither is it that the steam horses cannot take their amount of food; on the contrary, the tendency is rather to overfeed them at such times, so that the reduced speed has no compensating economy, but the whole effect is direct loss. What, then, should prevent the council of such an institution as this submitting that some definite means should be taken to overcome this disreputable fact, which has exposed us to so much public loss up to the present day? There are men of talent in the country who can discover a remedy, or who, at all events, can show us that it cannot be done, and then we may find out some substitute in place of a remedy. I attribute our neglect of this point entirely to the fact of the Government condemnation of iron ships hitherto as being unfit for the purposes of war. Had it not been for that most unjust and impolitic condemnation, I believe a remedy, or a substitute, would, as a great national object, have been provided long ago."

Two explanations are necessary to give full effect to the meaning of this speech. In the first place we must bring again to mind that the then apparently incurable disadvantages of the corrosion and fouling of iron ships had so alarmed the Admiralty in 1847 that the sale of the iron ships in our naval service was actually commenced. The persuasive eloquence of the projectors of anti-fouling and anti-corrosive compositions however had a happy influence upon the fate of the British iron navy, and the recalling of that desponding fiat is really the only good that ever has been—and in all human probability ever will be—effected by those senseless and fallacious nostrums. In the second place, we should observe that when copper is put upon and in connection with iron in sea water, not only is the waste of the iron terrifically increased, but the copper itself on the other hand becomes totally inoperative and entirely ineffective. It no longer degrades; it is electro-chemically preserved. It no longer maintains, as it would do

upon wood, a clean surface; exfoliation no longer takes place, and in proportion as the superficial area of the iron approaches that of the copper so will the latter be more and more coated with thicker and thicker deposits of the carbonate of lime and magnesia abstracted from the sea water, until the whole of its anti-fouling character is lost and the ship might be but an encrusted rock, covered with luxuriant fields of sea-weeds and adherent molluscs floating upside down.

This fouling is exceedingly expensive at all times, but it would be particularly perilous and vexatious in that of war, to be obliged constantly at short intervals to send our large transport and iron-clad ships into dock for cleaning alone; the retardation of the speed, too, of such vessels whilst at sea is a most serious item, not only in regard to their effectiveness when in pursuit of, but when brought into hostile collision with the enemy. Even in money expenditure it involves a really reprehensible waste. In respect to the mere operation of cleaning, it is notorious that many of our wealthiest shipowners and some of our finest commercial companies prefer to let their vessels run considerably fouled rather than incur too frequently the expensive operations of cleaning and scraping in dock. It may be also said that the merchant shipowner experiences an additional loss in the laying by of his ship, for it is the most active employment of his vessel that produces the most profitable result.

Again, the immense size of our iron-clads would render delays in getting into dock on account of insufficiency of tides, constant occurrences, while similar delays would also happen in respect to their liberation. Long and dangerous absences would thus be common amongst the vessels of our fleets; and more than possibly at the very time when our utmost naval strength would be wanted, half our vessels might be away, either in dock cleaning, or returning home for that purpose, or on the voyage out again after the operation had been performed. Let us, however, look for a moment, as closely as the little light that has been permitted to be shed on the subject will allow, at the money cost involved by this fouling.

The *Diadem*, 800 nominal horse-power, burns 60 tons of coals a day, and does nine knots per ton burnt. Now, if the loss from fouling amounted to one knot per ton burnt, the waste per day of steam fuel would be £14, adding to which the extra cost of wages for the loss of time on a long voyage or a naval cruise, and other items, would bring the loss to something like £26 a day. Again, if the *Warrior*, 1,250 horse-power, and burning not less than 100 tons of coal a day, should lose two knots an hour, or one-seventh of her speed, by fouling, the utterly wasted cost of this deterioration of speed—for be it remembered the full quantity of combustion that would give the highest speed with a clean bottom is required to attain with a foul hull this lower rate—would be, supposing English coal were used, £30 a day; and if fuel had to be bought at foreign stations—a most probable and frequent necessity—this expense would range from any increase up to more than double. When to this cost of fuel we add wages and other incidents we shall find that the estimate of £40 a day formed by Admiral Halsted in 1861 of the money value of the loss in this vessel is really within the mark, and entirely within the actual expenditure. With 30 vessels afloat, and assuming the average loss from each as £30 a day, the total waste for the whole fleet would be £900 per diem, or £329,500 a year from this one source of fouling alone.

In the face of all these evils there is but one hope for the practical application of copper. It is the perfect insulation of the sheathing from the ship. This is the point where Mr. Daft began, and no man has been more successful than he has in this direction.

In the year 1849, impressed with the importance of preventing iron ships from fouling, and protecting them from corrosion, he made his first step by coating the famous *Muntz's* metal with an insulating material upon one side, in order to prevent galvanic action being set up when such metal was applied to the skin of an

ron ship. He succeeded at that time in firmly attaching sheets of pure vulcanised india-rubber to sheets of yellow metal, and when the coated sides of these sheets were placed against the hull, the yellow metal was as perfectly insulated from the iron as it is possible to insulate metals in sea-water.

The extra care required in the workmanship, and the high price of the copper, were circumstances tending much against the system of insulated copper sheathing, however desirable it might otherwise be. But the fatal objection was that, no matter what might be the care, no matter how perfect the insulation, the connection of the two metallic elements was ever liable to be made by a variety of accidents, indeed, even the overhanging of the anchors, or of an iron chain, might be the medium of setting up destructive galvanic action in a fully sheathed ship.

But there is a still more costly and even more fallacious attempted avoidance of the difficulty. I mean the faint-hearted compromise between iron and wood. Iron ships are not kept clean at sea; wooden ships copper sheathed are. Therefore, say the compromisers, let us build ships with iron frames and wooden skins, that we may nail the copper on their hulls. Composite ships are the disgrace of the age; they are a standing reproach because they are sneaking confessions of failure and incompetence. Who that knows the value of iron, that has taken action in, or even but watched, its manufacture and its practical treatment in any of its multifarious applications, but feels the same glowing pride in its stalwart strength, its metallic muscle and fibre, its reliability and thorough powers of endurance, as he does in his own birthright to the name of Englishman, and but thinks all the higher of his countrymen that they are unsurpassed as iron-workers.

Convinced that the system of insulated copper sheathing was and ever must be imperfect, Mr. Daft turned his attention to another metal—zinc, and at the same time set himself to overcome the difficulties which had been experienced in attaching the copper plates to the iron hull. Cement and all sorts of adhesive compounds had turned out complete failures, and nothing but the old plan of nailing the sheathing on, as it was done upon wooden ships, seemed likely to answer.

To make an iron ship and then to cover it over thickly with wood—to put, in fact, the iron ship inside of a wooden one—seemed to him, as it must still do to every competent person, a most undesirable and unscientific procedure. Having by his experiments convinced himself thoroughly of the value of zinc sheathing, he devised the most simple and admirable plan for the firm attachment of the plates that could possibly be desired, and in doing this he has made the most important improvement in the construction of the iron ship itself. The butt-joint was the weak part of the ship; Mr. Daft wanted a groove around every one of the skin-plates which he could fill with wood, as the medium to which to nail his zinc sheathing plates, and in getting his groove he got rid of the butt-joint. But of this, hereafter; for the present we have to deal with zinc.

With zinc sheathing we have the following advantages:—It is one-third the price of copper, or yellow metal; it requires no insulating material, nor anything whatever interposed between it and the iron skin of the ship; it electro-chemically protects the iron, and is itself degraded and imperceptibly peeled away by the same electro-chemical action; it keeps perfectly bright and clean, and is as durable as copper or Muntz's metal.

Of these assertions some proof will naturally and properly be asked. Cabinet experiments might be possibly deemed not sufficiently practical upon such an occasion as the present, however interesting and instructive. I bring forward, therefore, the results of actual trials of the system made by the government.

After proving the value of zinc as a sheathing for iron in sea water, in conjunction with the "Special Committee on Iron," in 1863 and 1864, Mr. Daft

received instructions from the Lords Commissioners of the Admiralty, on the 18th February, 1866, to visit Portsmouth-yard, in order to see that certain experiments with two plates upon his plan were satisfactorily made for testing the efficacy of zinc sheathing for iron ships.

Two plates were made up of $\frac{3}{4}$ -inch plating, with $\frac{1}{2}$ straps at the back or inside, so as to represent the actual plating of a vessel of some 3,000 or 4,000 tons, and grooves according to Mr. Daft's patent were left, of $\frac{1}{4}$ -inch wide, between the edges of the plates; these grooves were subsequently filled in with teak strips, and the surface made fair and flush. The plates were encased in teak frames and backs, made waterproof, so that they (the plates) should have their faces or outsides only exposed, as in the case of an actual vessel. Mr. Daft's original intention was to nail on the zinc sheathing direct against the bare iron, in order that the contact between the zinc and iron should be perfect, and that the necessary amount of electro-galvanic action should be set up when the plates were lowered into the water to keep the zinc exfoliating or peeling away at a rate which would keep them clean and bright; but by instruction the iron was coated all over with a composition in fashionable use in Her Majesty's dockyards—Mr. Hay's glue—and contact had therefore to be established by using nails for fastening on the sheathing long enough to go through the teak-caulking in the grooves and to turn against the iron at the back of it. A few iron nails—common clouts—were introduced, in order to establish firmer and more enduring contact, and to prove that they might be used, if not to advantage, certainly without detriment to the work.

The unfortunate interposition of an insulating substance between the zinc and the iron would have rendered the former liable, but for the action established by the long nails, to foul to a certain extent. In fact, the insulation directed, would, if it had not been practically subverted by this means, have produced in the experiment results parallel with the case when zinc is used for sheathing wooden vessels. This test was a source of anxiety to Mr. Daft, which was only dispelled when, on the 12th Oct., 1866, the plates were raised for preliminary examination (as they were to be twelve months under water for the trial). At this examination, after six months' immersion, they were found perfectly clean, though not bright, as would have been the case had the chemical action not been checked by insulation. The zinc had not wasted enough. An ounce per foot per annum—the rate at which it had been disappearing—was not sufficient to ensure a bright surface, a bright metallic surface being that of all others the most to be desired for obtaining speed in iron ships or wooden vessels. This fact, that the zinc could be kept perfectly bright, having been thoroughly established previously by Mr. Daft, induced him to cause a third experiment to be made at Portsmouth.

At the end of the year of trial, a correspondence took place between Mr. Daft and the Admiralty as to raising again the two plates; but, as summer was approaching, it was suggested by the Admiralty that they had better remain three months longer. They were thus doomed to go through another season for the rapid growth of weeds and barnacles, which, as any naturalist will quickly perceive, was subjecting them practically to another year's trial, by including two spawning seasons of the barnacles and molluscons animals, and two seasons of the fertilising periods of the seaweeds, giving the plates, in fact, a double chance of fouling. This suggestion was, however, readily agreed to by the inventor, and when they were taken up for the inspection of the Lords Commissioners of the Admiralty, on the 12th of August, they were found still in a state of the most perfect cleanliness, though, as before, not bright. About the frame, and on the iron chains in which the plates were swung, were immense quantities of barnacles and weeds, but not a vestige on the plates

Mr. Daft then suggested that one or both plates should be stripped, and everything—zinc, nails, teak, iron, &c.—thoroughly overhauled, and an accurate account taken of the loss of the zinc; and this was, he believes, with respect to one plate, accordingly done. Not that the "authorities" have furnished him with particulars, but having asked for that favour he is in hopes of getting them. However, it may be asserted without fear of contradiction, that the zinc had lost only at the rate of exactly 1 oz. per foot per annum. It would be better that it should lose double that quantity.

One ounce per foot per annum is not much more than zinc sheathing loses on wooden ships, where a very feeble galvanic action indeed exists, and possibly at times none at all, when fouling more or less occurs. Not, as we have already stated, that fouling is peculiar to zinc alone, for other sheathings—copper and yellow metal—foul to the same extent as iron or zinc, or any other metal, when their condition is made negative in an electro-chemical sense. If, for example, contact with iron and copper and yellow metal be made in sea water, then yellow metal and copper will foul rapidly at the expense of the certain destruction of the iron—the positive metal. Mr. Daft thinks that in order to wear out the old wooden ships with as little expense as possible, and yet keep them useful and safe as long as they could be, it would be wise to use iron nails and zinc sheathing, for the zinc would preserve the iron fastenings about the vessels, and the clouts (iron nails) in the sheathing would hold the zinc on longer than zinc nails, and materially aid in keeping it clean by increasing its exfoliating qualities. Zinc for wooden ships under this treatment would become equal to copper or yellow metal for cleanliness, would last quite as long, and would cost not more than one-third the price.

To ensure a thoroughly clean surface, the "peeling away" should go on at a rate of not less than 2 ozs. per square foot per annum. At that rate it is kept absolutely bright, and may be still further increased to $2\frac{1}{2}$ ozs. by leaving certain parts of the hull unsheathed—for example, the keel, stem and stern posts, &c.—for by exposing a greater proportion of iron than zinc (within certain limits) the zinc is more rapidly destroyed, while, as I have in another place shown, the uncoated iron is, notwithstanding the immediate absence of zinc, kept free from fouling for some reason that at present I fail to perceive.

An exceedingly useful feature is the power that is possessed within certain limits of thus modifying the electro-chemical action on the zinc. There is a definite relationship between the extents of the surfaces of the iron and the zinc, and the rate of the exfoliation is in exact proportion to the areas of the two metals. The electro-chemical action can therefore be modified, accelerated, or retarded, according to requirement, by the proportion of the ship that is sheathed, or by internal plates in connection with the bilge-water. Thus, sheath one-quarter of the iron, you give half the superficies of zinc to iron, and in this state, when immersed, the destruction of the zinc is at a medium point, and the iron is perfectly protected. Now reduce the sheathing to $\frac{1}{4}$ th = $\frac{1}{4}$ th of the surface, and you increase the destruction of the zinc, but the iron is still fully protected; still further reduce the zinc to say $\frac{1}{8}$ th = $\frac{1}{8}$ th the surface of iron, and you arrive at the maximum destruction of zinc. Go further in this direction, and you do not increase the destruction of zinc, but you enfeeble the protection of the iron.

Entirely cover a surface of iron with zinc; you then have two to one of iron; in this state the exfoliation of zinc is feeble, but quite enough to keep it bright in sea waters. The iron when completely covered is, of course, fully protected by the electro-galvanic action exerted upon the zinc, and, in fact, a singular proof of this has just occurred in the Admiralty specimens inspected by the Lords at Portsmouth. A plate, grooved and caulked with teak, about 2ft. 1in. by 1ft. 4in. was partly plated

with zinc, in order to try the comparative result, the margin of bar-iron, about 3in. wide, was left around the sheet of zinc. This specimen had been under water about ten months; the zinc was beautifully bright & clean; the margin of iron was only coated with a slimy slime, which, upon being rubbed off by the finger, left covered a bright clean surface; the wood frame about this specimen, which had been fixed to it for lower it into the water, was an enormous mass of poly barnacles, and weed, thus proving that the zinc had protecting effect to some distance beyond the actual surface covered by it.

The moment we come, with a proper knowledge of the natural history of the subject, to investigate its nature and character of fouling, and what should properly be its most perfect prevention, we come inevitably to the unalterable conviction that all anti-corrosive and anti-fouling paints can never be any more than the merest nostrums. Barnacles do not feed with their feet, oysters do not imbibe nutriment through their shells, mussels derive no vital sustenance through the ends of the byssus by which they moor themselves. *Securaria* are not like land plants, which take up their supporting fluids by the fibres of their roots. The "root" of a seaweed is no more than the mere disc of attachment, the leather "sucker" which holds it to the bottom of the side of the ship. The idea, therefore, of painting compounds for painting a ship, with the view of killing the barnacles, shell-fish, and seaweed, is to the mind of a naturalist much on a par with a project for poisoning man through the sole of his boot. The individual who should propose to smear the ground with phosphorus and arsenic to destroy an invading enemy would be sent to Bedlam, but the quack who offers arsenical or phosphoric soaps for ships' bottoms sells his wares to injure no one but his customers.

There is another view to be taken of the natural history of shell-fish and seaweeds. All the things that attach themselves to a floating ship only stick to it, and the proper cure therefore is never to leave it any surface to stick to. Why copper on a wooden ship keeps clean is because it never has a permanent surface, and it is evident nothing can long adhere to a surface that is always dissolving away. Now, it is in the young state that either marine organisms or vegetables have the power of attachment to foreign bodies. Fix an oyster from its bed, or a seaweed from its root, and neither is ever a fixture anywhere again. If then, the minute young only of shell-fish and the minute seeds only of sea-weeds possess either free or involuntary locomotion, it is clear they can only adhere to very minute portions of any solid surface, and, therefore, as the extent of their adherence is not larger than the exposed surface of a metallic particle, it is evident that the exfoliation of that particle will carry away with it the minute organism attached; and it is also as evident that as that organism has only once in its life the power of attaching itself, its capacity of individually contributing to the fouling of any ship is gone for ever. The exfoliation of the metal of a ship must, therefore, be constantly going on. The voyages which the vessel undertakes will take her from winter in one latitude to spring time and spawning and seeding season in another; and wherever and whenever the myriads of young mollusca, cirrhipedes, serpulæ, corallines, bryozoa, and teredines, swarm in the sea, then and there will they seize upon every bit of the vessel within their reach, and so long as the surface of the hull remains will go on growing and prospering to the serious detriment of the progress of the ship. It is equally evident, under this aspect of the case, that fouling can never be prevented by any vitreous or glazed substances attached to the hulls of ships. However smooth or polished, however slippery any absolute solid permanent surface may be supposed to be, young barnacles, oysters, mussels, take too good a hold upon it, and the little floating seeds of sea-weeds stick too close to it ever to

slip off, and can only be got quit of by being "slipped away with" by the flaking of the surface itself.

Needless as any proof on this subject would thus appear to be, it is, nevertheless, imperative to put in an example or two of actual results of anti-fouling paints. These results are of two distinct characters. One, the effects produced in respect to the fouling of the hull; the other, the effects produced upon the iron, for many of these anti-fouling and anti-corrosive compositions are by no means innocuous to the constructive material of the ship. I really am very sorry to select "Hay's anti-fouling paint" as an illustration, because Mr. Hay is the Admiralty chemist, and his "composition" is under the immediate patronage of the Admiralty. But I take it because it should be, from the recognition it has received, presumably the best of its class; and because, if I did not take it, I should hereafter most probably be accused of having insidiously picked some inferior example, designedly leaving out the very one I ought to have brought forward in justice to the anti-fouling painters. I quote from the *Times* of 18th November, 1864—not an unfriendly organ towards the dockyard officials:—

"Notwithstanding the numerous descriptions of what are termed 'anti-fouling' mixtures, which have been submitted to the Admiralty, no discovery appears as yet to have been made of a preparation for effectually preventing the accumulations of animal and vegetable matter over the hulls of iron vessels.

"Although the bottom of the iron frigate *Achilles* was coated over before her launch with the 'anti-fouling' composition of Mr. Hay, the Admiralty chemist, so foul had the bottom of this vessel become while lying in Chatham harbour, preparing for sea, that in the run from Chatham to Devonport her speed fell off more than three knots an hour from her steaming rate on the occasion of her official trip at the Maplin Sands.

"When docked at Devonport, the bottom of the *Achilles* was not only foul, but many of the plates were left completely bare of composition, while corrosion had in many cases eaten away the plating to the depth of from one-sixteenth to one-tenth of an inch."

I can add my own testimony, having seen the *Valiant* put into dock a short time ago, after 16 months in harbour, that the condition of Mr. Hay's composition, or of the iron vessels coated with it, has been in no wise improved; nor can I conscientiously say one single word in favour of any other of the "compositions," anti-fouling or anti-corrosive, with which various portions of that noble iron-clad was besmeared. Mr. Hay's compound has a basis of copper, and the hull of the *Valiant* was deeply eaten into by the galvanic action, as well as thickly and totally encrusted with a bronze-coloured oxide. It certainly was not so foul as some other portions of the ship, but it would not have been even in a semi-clean state if it had not been "hogged" by some new patented scraping machine before the ship came into basin.

Doubtless I should find I had left a hole in the armour of my argument if I omitted to say a few words upon the other metallic paints in which other metal bases are used—as red lead, quicksilver, and zinc. I assert of all such, without fear of defeat—contradiction on all points I know I may expect—that no paint having the oxide or other salt of any metal can possibly be of any use in the prevention of fouling; and not even if the absolute metal itself in a pulverized state could be mixed in with the oil, varnish, or other medium, would such a paint have any preventive influence. Take zinc itself in fine powder, for example; it would be utterly useless, because each particle of the metal being encased in and insulated by the medium of the paint, galvanic action would be stayed, and there would be no exfoliation of the surface—the sole means of avoiding marine foulness. In the cases of red lead, mercury, plumbago, and antimony, if they have any effect at all, it will not be upon the barnacles and sea-weed,

but upon the iron hull; and this any action they may exhibit will not tend to improve the condition of. Some owners use merely a thick coating of simple grease for ships going on distant voyages, and so long as the friction of the water can carry off the weeds when they have acquired a certain size, it may possibly do so as long as the grease lasts—but what then? Fouling of the iron hull of course sets in. How far efficacious this plan may be, in even its best circumstances, I know not, but this I do know, that one large house that has wisely eschewed anti-fouling compositions, and uses this less hurtful means, pays probably the largest sums, and certainly takes more care and pains in docking, scraping, and painting its ships than any other in the port of London. And it is well repaid for this expenditure. Paints of all kinds must be peculiarly liable to be rubbed and scraped off, and of course the iron hull over such portions would then be completely unprotected, and fouling and corrosion would go on as it pleased.

I have been thus severe, but no more so than is deserved, upon paints and coating compositions of all kinds, because one of the antagonisms zinc sheathing has to encounter is the notion entertained by sailors and owners, and particularly the former, that they should have "something to paint the ship with." A sailor naturally likes to paint his ship, for much the same reason as a child his toy-boat; and owners abide by paint for their iron ships because they don't know what else on earth to do with them; and because to sheath them with copper is highly dangerous, as well as expensive.

Another antagonism to the trial of zinc sheathing amongst merchant shipowners, is the objection they have to having anything done to the skin-plates for the purpose of securing the sheathing. Mr. Daft effectually secured his insulated copper by drilling holes partly into the thickness of the skin-plate, and plugging them with wood or ebonite, and then driving the nails which secured the sheathing into these plugs. For myself, I see no objection whatever to this plan, but shipowners are excessively timid about the slightest mechanical operations, although they have no suspicion or fear of chemical action being painted all over their ships.

We have so far taken a broad survey of the nature, character, and action of zinc sheathing; and are brought now to a consideration of the best way of putting it on.

It appears, then, that in order to perfectly protect iron hulls for an indefinite period from corrosion—in fact, to preserve their thickness in its full and original integrity, until every other part of the vessel is thoroughly worn out—we have only to plate the bottoms in a simpler, cheaper, and safer method than has ever before been done. This Mr. Daft has accomplished by making all the joints lap-joints, and entirely avoiding butt-joints and their costly and evil consequences. To make the laps fair and flush and perfectly water-tight, they are, in addition to the ordinary punched caulking (if that be thought desirable), caulked with properly prepared strips of compressed teak, and then the zinc sheathing is most firmly secured by nailing on the sheets to the teak in the grooving in the ordinary manner of fastening copper sheathing on wooden vessels, the zinc being, at one and the same time, the complete preserver of the iron hull and the essential metal for keeping the bottom perfectly clean for a number of years proportionate to the thickness of the sheathing used. If, for example, a sheathing of one-twentieth of an inch thick be used—as a good stout sheathing fit for a vessel of 3,000 to 5,000 tons would be—it would weigh 30 ozs. to the square foot and assuming a loss of 2 ozs. per annum, and that when it was reduced to half its thickness re-sheathing would be required, we have at least seven years of a clean and safe bottom without the least anxiety about it as to fouling or corrosion. It is important in its place to determine the size and shape and appointments of our new iron fleet, but it seems out

of place to do anything before the very base and foundation of the superstructure be settled. If our magnificent broadsides, cupolas, monitors, or whatever we may come to, be dependent upon any description of paints or compositions and be really wanted on service, they must all go to ruin by corrosion before the end of a commission, or come into dock every six months to have their hulls cleaned and re-painted, to say nothing of the diminished value of a vessel which begins to foul from the day she leaves port, and gradually but surely gets worse until her boasted speed is reduced to two-thirds, and even to half its original rate.

Almost all iron ships as now built present longitudinal rows of plates alternately projecting and receding—"in and out strakes," as they are called by ship-builders. In these strakes the joints are of two kinds—one made by the over-lapping of the edge of one plate upon another, and called the lap-joint; in the other, the edges of the plates are planed smooth, and the ends brought close to each other, the joint being made good by the riveting of the ends of both plates to a common back-strap. That is termed a butt-joint, because the two ends merely "abut" against each other. The lap-joint is in every way by far the stronger; the rivets penetrating both plates, and being driven in red hot, by their shrinkage exert such power that the lap-joint, if properly made, is absolutely stronger than the plates themselves. But such is not, and never can be, the condition of the butt-joint. That is a form of joint that in its essential character is the very weakest possible. It is really of the nature of a plate half cut through; and a very correct general notion of its condition may be given by comparing it to a plank sawn across to the half of its thickness. Because a saw-cut was formed of three pieces, a plank cut quite through and a back piece, it would not cease to be a saw-cut, and just so, although the butt-joint is formed of the two ends of two plates and a back-strap, the line of particles in that back-strap facing the seam between the ends of the plates will be that portion of the metal which will have to endure all the strain brought upon the joint. A saw-cut weakens a plank more than the proportion of its depth to the original thickness, because there is a leverage of the substance of the wood, brought to bear during any strain, that opens the cut upon the front line of particles of the uncut remainder of the plank, and which is thus liable to be rent asunder, and in this way the crack is easily continued. The back-strap of a butt-joint is always in the condition of the remainder of a saw-cut plank; and, as such butt-joints are used for the vertical joints of the strakes, there are many hundreds of such butt-joints in a ship always liable to be strained open and split, and that, too, it may be all over the ship. When vessels strain across ocean waves the butt-joints are exceedingly likely to give way, and many iron vessels have gone down from no other cause than the opening of their butt-joints. When iron vessels are strained, it is usually along the lines of butt-joints that they part asunder; and, in brief, all the accidents that arise from the defects of, or strain upon the fabric, may be set down, with hardly an exception, to the giving way of the butt-joints. No one ever heard, that I know of, of lap-joints, where the workmanship was good, giving way; but the iron-shipbuilder prides himself upon the finish of his butt-joints, and thus in the very pride of his craft confesses the inherent deficiency of the butt-joint. Why should he pride himself upon the extra care and finish bestowed upon it if it were as good as the less cared for lap-joint; and why should he use the lap-joint for his horizontal strakes, and make an uneven irregular hull for the ship, when with the butt-joint he could make a fair and flush hull if the butt-joints were not inherently worse? He certainly would reject the lap-joint if it were not for its superior strength. But the weakest part of a ship is its actual strength, and therefore as the lap-joints are its strongest parts, the butt-joints detract from the entire stamina of the vessel. Now, in putting the groove round each

plate for his infilling of teak, Mr. Daft uses a plan which entirely gets rid of the defective butt-joint altogether out of the ship. By putting the plates an inch apart he takes the joint out of the category of a saw cut, and by putting a narrow plate of the same thickness as the skin of the ship at the back of the joint he virtually reduces the in strake from three feet wide to one inch in width. It is still, however, of the nature of a strake; and the metal of the inner plate, when any strain comes upon it, has sufficient extent of surface to bend into an arch, and, no single line of particles having to bear more than its proper share of the strain, there is no longer any liability for the metal to be pulled apart or to crack. The extravagant expense of planing the ends of the iron skin-plates is entirely done away with, the edges of the plates being left just as they come away from the shears, and the teak, carefully dried, compressed and forced tightly in, securely caulks the joint, and makes the entire surface of the hull perfectly fair and flush. The whole construction of the ship under this process will be quicker and cheaper than ever: there will be no inequalities in the rigidity or strength of different portions; no sharp edges to encourage the commencement of oxidation and fouling; and there will be the most suitable means of nailing on a metal sheathing to protect the iron hull from corrosion from salt water when afloat. What Mr. Daft has done really is to have turned the insecure butt-joint into double lap-joints; the result is mechanically right, and the wonder is that it was not seized upon by every builder the moment it was devised. But strong is the force of habit; and it is a common failing of men to cherish most highly that which has given them the most trouble. Troublesome things, however, like troublesome people, are seldom good for much.

Both subjects, the construction of iron ships, and zinc sheathing, permit a great deal more to be said about them; but a paper for a society's evening meeting cannot go to the extent of a volume. I will, therefore, only add that, as wooden ships are still built in large numbers for foreign voyages of long duration, solely because of the fouling of iron ones, I do believe the adoption of Mr. Daft's process of zinc sheathing, by enabling iron ships to undertake voyages of any length of time in a perfectly clean state, will throw into the iron ship building trade all the orders that would otherwise go, as now and heretofore, to the builders in primal wood. Iron ships are incomparably stronger, and are much lighter than wooden ships and can be made on finer lines.

I now ask full discussion on these subjects, in which, I have become interested in the firm conviction of their correctness and importance; and which, for those reasons, I wish to see put to practical trial by shipbuilders and shipowners.

DISCUSSION.

MR. HADDAN said, he was afraid that Mr. Mackie had sought to prove too much, for this reason—that if all he had stated was correct, iron vessels would wear four or five times as long as they do now, and, consequently, the trade of shipbuilding would be reduced to the extent of four-fifths, unless a very greatly increased demand for ships arose. He had himself tried to induce people to make important changes in materials for manufacturing purposes. Some years ago he brought forward a plan for building railway carriages with *papier-mâché*, which would last twenty years; but on introducing the subject to a carriage builder, he would not entertain it for a moment, because, he said, he did not want carriages to last for twenty years, for if they did, what would become of his trade? But, he added, if he could show him a plan by which they would last only a year, he would take it up. He could hardly suppose that the Admiralty authorities of the country were influenced by these feel-

ings, but he thought that they were in the habit of waiting to see what other countries did; and he believed, if Mr. Mackie or Mr. Daft could induce the Emperor of the French to try this plan of zinc sheathing on one of his vessels, and it succeeded, our government would adopt it instantly. He considered this invention a very important one. He was not a shipbuilder, but understanding something of the properties of iron, and hearing the explanation of the system which had been given this evening, he believed it to be a sound one, and he hoped public pressure would be brought to bear upon the government to give it a fair trial.

Mr. G. B. GALLOWAY submitted that the question before the meeting was one of paramount national importance. He would refer to a statement which was made in this room at the meeting of the Institute of Naval Architects in 1865, by Sir John D. Hay, one of the present Lords of the Admiralty, who said that unless some mode were discovered to preserve the bottoms of iron ships, in a short time we should have no iron navy in existence. He (Mr. Galloway) begged to ask the author of the paper at what dates the tests of this invention had been made under the auspices of the Admiralty authorities?

Mr. MACKIE replied in 1863 and 1864, at Shoeburyness, and from 1865 up to the present time at Portsmouth.

Mr. GALLOWAY said the quotation from the *Times* which had been read, lamented that no discovery had been made for the preservation of the bottoms of iron ships, while they had the fact before them that these tests were made prior to the date of that article, when proofs had been afforded that this system was most certainly a valuable one. It was a national disgrace that, in the face of this invention, there should still be going on the enormous waste of public money resulting from the fouling of the bottoms of our iron navy.

Mr. C. F. T. YOUNG said he had listened with great satisfaction to Mr. Mackie's paper. He had had many opportunities of observing the evils which resulted from the fouling of ships' bottoms, the effects of which had been in no way exaggerated by Mr. Mackie. The idea was still held that the copper bottom of a vessel kept clean because it was of itself a poisonous material. However poisonous it might be in itself, it had not a destructive effect upon the organisms which infested the bottoms of ships. The rapidity with which this fouling proceeded was hardly to be credited. The Southampton pilot boats, during the summer months, had to lie ashore every fortnight to clean off the fouling, and the St. Maur pilots had to do the same. It was stated that on the *Gloire* and other French iron-clads had on an average passed 55 days each in dock during a period of little over 14 months, only to remove the fouling. With regard to the cost of keeping ships' bottoms clean, it was stated that the P. and O. Company spent £70,000 annually, simply for keeping their ships' bottoms clean. One iron ship of 800 tons, which had been eight months in a warm latitude, had 30 cart loads of barnacles taken off her bottom, an estimated weight of 28 tons. It was calculated that our iron-clads had each to spend 14 days every six months in dock to remove the fouling, although they were frequently hogged. The iron steamer *Megara* was found to incur an increased cost in running of £23 per day through having a foul bottom, the same amount of fuel only producing seven knots an hour in place of ten. It had been proved, from careful tests made with the Dublin and Holyhead mail steam packets, which were very fast boats, that, after they had been out of dock two months, their speed uniformly fell off from half a mile to one mile per hour, from fouling only. With regard to the alleged poisonous effects of copper, anyone who had seen the oysters on the coast of Cornwall knew that they were perfectly green coloured from being impregnated with copper, so that it was impossible to eat them, and yet they lived and thrived. Eighty tons of barnacles were taken off the copper bottom of an old wooden ship

which was broken up some years since. About a year and a half ago an experiment was tried, at the instance of the Scottish Shipbuilders' Association, as to the powers and advantages of the so-called poisoning process. The four quarters of an iron plate were each thickly coated with the most poisonous compounds that could be found—arsenic, corrosive sublimate, &c., and the plate was immersed in sea-water for some months. When taken up it was found to be in the most foul condition possible, and it so happened that the largest barnacle of all had placed itself at the junction of all the four compounds. It would hardly be believed that there were persons who, even at the present day, would deny the existence of galvanic action; but it would seem that this idea was held more generally than would at first be supposed, when we found the use of yellow metal and copper on iron ships still adhered to in the navy. Mr. Young called the attention of the meeting to a piece of iron plate on the table, which had been experimented on, by covering it with Muntz's yellow metal, insulated from the iron by vulcanised india-rubber, and although the edges were protected so that no water could get between the copper and the iron, yet, after having been immersed for several months, the iron was found to be very much eaten away, owing to the galvanic action. The *Achilles*, when docked at Plymouth, was found to have her plates eaten in from $\frac{1}{16}$ to $\frac{1}{8}$ of an inch deep, and was very foul. Numerous other instances were given. The *Royal Oak* iron-clad, with a coppered bottom on a wood sheathing, was found to have had her plates eaten by corrosion to the depth of three-eighths of an inch in less than eight months. With regard to the employment of poisonous paints, if the barnacles held on by their mouths there might be some sense in using them, but they hold on by their feet instead. Some of the barnacles taken off a plate painted with arsenic were boiled and given to a cat, and the animal died with all the symptoms of arsenical poisoning, while the barnacles themselves remained wholly unaffected by the compound.

Mr. BOTLY said they were much indebted to Mr. Mackie for the paper he had read; it was a matter of the greatest importance, not only to the Society, but to the country at large, that such a subject should have been brought forward. The paper treated of two great improvements in the construction of iron ships, viz., the lap-joint for the plates, and the zinc sheathing as a protection against fouling. Both these matters were of the utmost importance, and deserved careful consideration.

Mr. CAMPIN asked whether the action of the zinc sheathing, in keeping off the barnacles, was supposed to be due to the electric current, or merely to the wearing away of the surface of the zinc.

The CHAIRMAN said the paper sufficiently explained that it was the slipping away of the surface of the zinc from the feet of the barnacles, by exfoliation of the metal, which kept the bottom clean.

Mr. BLACKIE inquired whether the zinc to be used for sheathing was prepared in any special manner, different from the ordinary mode of manufacture.

Mr. MACKIE replied that the zinc was prepared in the usual way. It might, however, be found desirable to adopt some annealing process, to get rid of any extreme rigidity of the metal.

Mr. BLACKIE remarked that those who had zinc water-cisterns would probably have observed that an incrustation took place on the zinc. He would like to know whether the action of fresh water on zinc was different to that of sea water.

Mr. MACKIE replied that fresh water would produce a deposit on the zinc by evaporation; but when iron was present, salt water set up a galvanic action between the two metals.

Mr. BLACKIE then called attention to the question of the expansion and contraction of zinc as compared with iron, and expressed his opinion that there was

liability of the zinc cracking. He would also like to be informed as to what would be the cost of plating a ship with zinc as compared with copper, the cost of cleaning being added. The cost of sheathing a vessel's bottom with zinc, he apprehended, would be considerable, and it appeared it would require to be renewed, owing to the wasting of the metal, in the course of a few years. The question, therefore, arose, whether the cost would not be greater than that of docking the ship occasionally, and clearing off the fouling.

Mr. E. J. REED (Chief Constructor of the Navy) said the paper appeared to be a very able and interesting one, but one or two things had been said in it which he could not allow to pass without notice. He thought the theory enunciated as to the weakness of the butt-joint, viz., that there was liability of the joint breaking at the line where the plates touched, was erroneous; in practice it was found that fracture, when it did occur, took place in the line of rivets. He did not say the butt-joints never broke at the line of junction; but, when they did so, it arose from the fibre of the iron in the butt-strap being put across, instead of lengthwise. His opinion was that, with ordinary good iron shipbuilding work, when pains were taken to put the fibre of the iron in the direction of the fibre of the plate, and with a slight increase of thickness of the butt-strap, it was not found that the butt broke in the way suggested in the paper. With regard to the subject of fouling, he might say that to his certain knowledge it had been a matter of most anxious consideration, and also of experiment, by the Admiralty ever since the introduction of iron ships into the navy. For two or three years the late Board of Admiralty and the Controller of the Navy sanctioned a large number of experiments with anti-fouling and other compounds, but with, he was bound to say, no very satisfactory results; indeed there seemed little promise of anti-fouling compounds doing all that was desirable in keeping iron ships' bottoms clean. He thought much was yet to be done in that direction; particularly by getting rid of the irregularities of the surface of the immersed bottom, and making it perfectly flush and even, so that it could be easily cleaned by being brushed while afloat, as was done in former times with wooden ships. But still he thought any advantage thus obtained would be very inferior to an arrangement which would secure a permanently clean bottom. The system described in the paper was certainly entitled to great consideration, in spite of any little difficulties that might at first appear to belong to it. For instance, at first their appearance to be considerable difficulty in caulking the joints, but his own feeling was that in a matter of this magnitude and importance mere mechanical difficulties of this kind would soon be got over. We had already encountered, and were still encountering very much larger difficulties, and we could not now afford to be deterred by trifles from adopting any real improvements. He might, however, say that no experiments had yet been made with this invention, which would carry complete conviction to the Government. The minds of all those persons who were responsible must first be fully satisfied. For his own part he did not attach much value to the experiments at Shoeburyness; moreover, they were on too small a scale to warrant the formation of any conclusion upon them. In many instances, no doubt, when the copper sheathing had been placed in contact with the iron, a most destructive galvanic action had taken place, but in the case of the *Royal Oak* and some other vessels, a layer of wood was interposed between the iron and the copper, and he could state that galvanic action had now been perfectly prevented. The inspection of ships on the Mediterranean station showed that the iron plates, insulated from the copper by only a single layer of wood, remained perfect. He entreated those who had the success of this invention at heart to make experiments on a large scale, such as would satisfy the Government. He believed the Portsmouth experi-

ments were valuable, though he knew they were not conclusive to some persons who saw them. The iron which was charged against the Admiralty in this matter was equally applicable to private shipowners, for he was not aware of this system having been adopted by any more than by the Government.

Mr. YOUNG remarked that it had been found that the wood sheathing on the iron plates was an insufficient insulation. This had been shown in the French and Spanish vessels. The plan might answer if the ships were not exposed to heavy seas; but by these and other violent shocks, contact between the iron and copper was often produced, and galvanic action was set up.

Mr. MACKIE, in reply upon the discussion, said he was glad to have had the pleasure of listening to the remarks of Mr. Reed. That gentleman, he was sure, knew enough of him personally to be quite aware that if he used strong language in reference to the proceedings of government, it was not out of personal animosity or a desire to attack the government, or their officials, but simply because one who attempted to set upon the inertia always existing in government departments must express himself strongly, or he would have no hope of being listened to. With regard to the question of the cost of sheathing with zinc it was stated in the paper that it would probably be one-third that of copper. The copper required to be replaced on wooden ships every three or four years, while zinc would last, at a minimum, from five to seven years, and might be made to last from twelve to fourteen years, according to the thickness of it. With regard to the question of the expansion of the zinc, he believed the difference in the amount of expansion and contraction between the zinc and iron would be very small in temperatures only ranging from 60° to 70° or 80°; it would not be greater than would be relieved by a slight buckling of the zinc plate. He had not been able to go fully into all Mr. Daft's ideas with regard to the jointing of iron plates, but he had no disposition to measure his own experience in that matter with that of a gentleman like Mr. Reed. He did not gather, however, that Mr. Reed considered Mr. Daft's joint to be weaker than the butt-joint. On the question of putting the copper sheathing on iron vessels over wood plating as an insulating material, he accepted Mr. Reed's statement of the result as perfectly correct. Still it was borne in mind that water would percolate wherever there was a crack, and so long as connection was made by the water between two opposing elements, so long as he thought there was danger of corrosion by galvanic action.

Mr. REED said he should be sorry it should be supposed that he had implied that the plan of placing the copper sheathing on wood, as an insulating material, was quite satisfactory. If the plan described in the paper were successful, it would be immeasurably superior.

Mr. MACKIE was glad to hear that remark from Mr. Reed. He agreed with that gentleman that it was essential this system should be tried on a larger scale than it had been; and that this might be done was one great reason for his bringing the subject before this meeting. With regard to the putting a wooden layer to receive the copper sheathing, there was this further objection to it, that whatever quantity of wood was put on the outside of the hull, it practically increased the size of the vessel, and, to that extent, increased the amount of resistance, and for every square foot of such increase there was a loss of one nominal horse-power. With regard to the carrying out of experiments on a large scale, he would ask the inventor of this plan bound to build a vessel at his own expense, send it to sea, and keep it there a sufficient time to afford a thoroughly satisfactory test of the merits of the system? Mr. Reed might possibly be right in saying that the experiments at Shoeburyness were worth nothing; but the experiments at Portsmouth were carried out under official authority, and he was going to

say nearly officially spoilt. If this system had merit, let it be tried on a proper scale; if it had no merit he (Mr. Mackie) would be amongst the first to give it up. By this system the sheathing could be applied to the hull of the ship direct. If it required any insulating material, however thin, it did not realise what was claimed for it. He might add that, if the Government took experiments in hand at all, the least they could do was to carry them through; because, if they did not, they put the inventor in an unfair position. He believed the system would have been tried in the mercantile navy ere this, if the trial experiments had not been in government hands; but that being the case, people naturally waited the result of the government trials. He, therefore, said, let the inventor try an experiment according to his own plans. Let him have some small iron vessel, even a condemned one, and let it be sheathed on his system. If, then, it was found wanting, let it be given up.

The CHAIRMAN said as to the importance of the subject treated in the paper there could be no doubt. It was a national question to overcome the difficulties which still attached to the use of iron vessels. Iron had been so completely proved to be the better material in naval construction that the Government had largely adopted it; and yet there was one defect attaching to it, viz., that iron ships would foul very quickly. The means hitherto adopted were clearly insufficient as a remedy for the evil. The poisonous compounds spoken of he thought might be fairly dismissed from their minds as being playthings in connection with a very serious subject. Copper sheathing appeared very inapplicable, for when in contact with iron it invariably had the effect of corroding it, because the salt water would percolate between the two metals; and moreover, the copper sheathing itself would fail in its purpose from the want of exfoliation of the surface. With regard to the insulation of the two metals by the interposition of a wooden layer, he agreed with Mr. Reed, that the iron would be effectually protected so long as no metallic contact took place. The moisture between the two metals would not be sufficient to set up galvanic action, the battery would be in the condition of an "open" battery, not a "closed" one. There was, however, great difficulty in maintaining perfect separation, because wire, even of $\frac{1}{8}$ inch gauge, was sufficient to transmit a considerable current, and produce a great amount of mischief upon the iron, and it was hardly to be supposed that the two enormous surfaces could be long kept perfectly separated without metallic connection being formed between them. What surprised him, somewhat, on hearing this paper was the very slow rate of exfoliation of the zinc. He had himself made experiments upon the action of the salt water upon zinc in contact with iron; and he found the zinc acquired weight up to about three months, but after that period a sensible diminution in weight took place. The author of the paper stated that the amount of the oxidation of the zinc was not more than $1\frac{1}{2}$ oz., or 2 oz., even if the exfoliation was made more active by an increased galvanic action. It would be interesting to ascertain whether there was any increased exfoliation when the ship was in motion. No doubt there would be some increase, but experiment would determine the amount. No doubt, chemically, zinc sheathing would protect the bottom of the vessel entirely, for even if a sheet of the metal were displaced, there would still be the influence of the zinc in contact with the iron. So far, then, the invention appeared to him to be an exceedingly promising one, and one which he thought should certainly be tried seriously by the Admiralty. With regard to the observations of Mr. Reed, he thought he had stated the case very fairly, and he believed personally he would be disposed to afford the invention every trial it required; but, if the experiment at Portsmouth was to be taken as evidence of the anxiety of the Admiralty to inquire into the merits of new inventions, he thought in this case an injury had been done to the

inventor. There was nothing, he thought, more destructive to the interests of an inventor than an imperfect trial.

Mr. REED thought it due to the Admiralty to say that the experiment was not initiated by them. They merely gave permission to Mr. Daft to put down some plates prepared on his system, but they were in no way pledged to go on with the experiments. At the same time, having gone to the extent they did, it might have been desirable that they should have continued the experiments further. He merely wished to say that the Admiralty did not initiate the experiments and then suddenly drop them.

The CHAIRMAN said that altered the case in some respects; but he maintained that even the sanctioning of experiments implied, he thought, a continuation of them; those who were practically acquainted with the difficulties appertaining to the introduction of inventions, would appreciate more than official personages could possibly do, the great hindrance caused by incomplete experiments to the progress of an invention. If the intervention of the Government were entirely refused, the inventor was free to act as he pleased; but from the moment he placed his invention in the hands of the Government, he was practically shut out from the public until a verdict upon it had been pronounced. He thought the Government might spend a few thousands a year very well in making really serious experiments upon questions of this nature. Even if such an invention as this were tried upon a merchant ship it would be no convincing proof to the Government of its merit. The Government must make its own experiments to determine its value. With regard to the mechanical mode of joining the plates, he thought it sufficient for this invention if it was admitted that there was no inconvenience thus caused. He did not think any great weight was to be attached to the question of the buckling of the plates; if the back-strap was carefully put on, there would be no fear of fracture unless, as mentioned by Mr. Reed, the back-strap had the fibre in the wrong direction. He thought Mr. Mackie had brought the whole subject very ably and fairly before them, and he was sure they could do no less than give him their thanks for having done so.

The vote of thanks was then passed.

Fine Arts.

ART AT THE PARIS EXHIBITION.—The competition in sculpture will be between France and Italy, each of which nations is remarkably well represented. The art of sculpture, however, from several causes, scarcely tells with the same effect in the Paris Exhibition as in the London. In 1862 the history of English sculpture was traced back to Chantrey, Flaxman, Bacon, and Banks, and the number of works exhibited amounted to 300. The difficulty and danger of transit may, in some measure, account for the fact that there are now not fifty pieces of English sculpture in the Paris building. The United States send Miss Hosmer's "Sleeping Faun," which acquired renown in the Dublin Exhibition. Italy again produces Magni's "Reading Girl;" also Migliorotti's "Charlotte Corday," a figure which appeared in the Royal Academy of last year. These and other like works are striking examples of the realistic school for which Milan has long been famous; the detail is minute; flowers, delicately and elaborately wrought, give decoration; and other accessories, such as the rush-woven bottoms of chairs, are faithfully rendered in marble. This realistic school, which never fails to attract the multitude, obtains impressive results in the studiously wrought figure by Vela, "The last days of Napoleon I." There is in this work a mental expression which in decorative schools is often wanting. Artisans will do well to study this manner of Milan, which has, in some measure,

grown out of the vast and long-continued demand for decorative sculpture for the cathedral. The style, it may be observed, is the reverse of severe and architectonic, and it has nothing of the Gothic or mediæval element. The Gothic of Milan Cathedral was due to a German; Italian sculptors are so much committed to Canova that they do not readily submit to northern styles. The architectural screen which leads to the Italian courts should be noted by the decorative artist, as a summary of the Italian *cinqus cento*. The three sister arts of architecture, sculpture, and painting are here associated after the manner of that epoch. The screen, or *façade*, is built up of columns, pilasters, friezes, cornices, &c.; statues occupy the niches; arabesques, both pictorial and bas-relief, run up the panels; the designs are derived from churches in Lombardy and the "Loggie" of Raphael. A *façade*, less decorative but yet cognate in style, has been put up by Prussia, which is fitting in a nation still swayed by the Renaissance. The Roman sculpture court is not likely to make a display equal to 1862, when it formed a marked attraction. It contains, however, a grand group by Luccardi, professor in the Academy of St. Luke, "An Episode of the Deluge," which serves as a striking example of the modern Roman school. There is none of the repulsive horror which a French sculptor has thrown into an analogous composition. The sentiment is softened by beauty; the execution has delicacy; the composition, too, has been nicely balanced. Tenerani, a venerable leader in the Roman school, is absent; the "Angel of the Resurrection," or "The Swooning Psyche," would have been welcome. The number of English sculptors resident in Rome who swell the contents of the Pontifical collection is less than in 1862; works, however, by Mr. John Adams and Mrs. Chomeley, may be noted; by the latter is exhibited an impressive head of Liszt, inspired by the portraits of Dante. It does not appear that the territories newly acquired by the kingdom of Italy have added materially to the picture and sculpture galleries. One painting comes from Venice, and a bust from Naples. Dupré, of Florence, as usual, asserts his individuality; his "Pietà," and a bas-relief, "The Triumph of the Cross," have an originality seldom found in the treatment of Christian subjects. Dupré, as the name implies, has more in common with French sculptors than Italian. The student, by a little attention, will not find it difficult, in the numerous works collected, to distinguish the schools into which modern Italian sculpture is divided. It will be well to remember that all spring alike from the Greek and ancient Roman; that the influence of Canova is for the most part patent everywhere, save when, by chance, a little naturalism has crept in. Beauty, imagination, delicacy of handling, with attendant weakness, characterize Italian styles.

COLLECTED WORKS OF M. INGRES.—The exhibition of the pictures and studies of this great French artist already referred to, has been, within a short time, opened in the Imperial School of Fine Arts, Paris. The artist's family and friends, and Government authorities in the departments, have combined to make the collection as complete as possible. Some important works, such as "The Apotheosis of Napoleon I.," are wanting, yet the selection made is sufficiently varied and thorough to enable the student to form a correct judgment of the artist's talents and style. Ingres was the representative of a distinctive school, and, as such, his works are specially instructive. He commenced as a pupil in the cold, classic, and statuesque manner of David, from which, however, he freed himself, even in his earliest works, executed at the commencement of the present century. Ingres soon transferred his allegiance to the Italian Renaissance at its point of culmination under Raphael. The works which now in Paris best represent this aspect of high art are "The Apotheosis of Homer," and "The Martyrdom of St. Symphorian." The style is directly Roman and not Venetian. Form, severe and hard, is dominant over colour; and the reflected lights and tones which the Venetians wrought into harmonies almost decorative in

brilliance, were by Ingres ignored as facts in nature. The artist was also known in the spheres of imagination and portraiture; "Ruggiero delivering Angelica," "Edipus explaining the Enigma of the Sphinx," "The Odalisque," and "Cherubini crowned by the Muse of Music," have long gained a European reputation. To professional painters, the very numerous studies are specially instructive. They are after the manner of Raphael and the great Italian masters. Each figure, every piece of drapery, is wrought from nature; and figures draped in the ultimate composition are often, in the first place, drawn as studies in anatomy. It may be also added that this collection is of the greater interest because it can never be repeated. The high historic school, of which Ingres was among his contemporaries the last representative, has given place in France, as in England, to styles of a more popular character. The opposing school of the colourists, under Delacroix, gained supremacy. But though few artists will now venture on methods fallen into disrepute, no one can study the works of Ingres without profit. They teach the value of form, and expression through form. In London, in 1863, the painter was represented by a picture which excited much attention—"La Source." The proceeds of the present exhibition will be devoted to the promotion of art.

Manufactures.

HOUSEHOLD BOILER EXPLOSIONS.—It is mentioned in one of the reports of the Manchester Association that six explosions happened during the frost in the month of January to boilers in household use, and set in the greater number of cases in kitchens. In most instances these explosions were attended with fatal results, there having been five persons killed, and four injured. Considering the number of these explosions, as well as their fatality, the subject appears to be one of much importance, especially (says the report) since those most exposed to injury are domestic servants, totally ignorant of the danger incurred, and so many of them appear to suffer from these explosions on the recurrence of every frost, and will, it is feared, continue to do so as long as the present construction of these boilers continues unaltered. It is reported that all the exploded boilers just referred to were on the circulating system, and it is thought that the construction generally adopted affords an easy explanation of the frequency of their explosion. These circulating boilers are for the most part constructed with an overhead cistern connected to them by means of two pipes, so that when the fire is lighted the steam and heated water rise through one of these pipes, and the colder water, from its superior gravity, descends through the other, and thus a regular circulation is set up, which continues as long as the pipes are free, the supply of water kept up, and the fire burning. No arrangement can be safer as long as these conditions are complied with. The surplus steam finds a free escape from the overhead cistern, while the two open columns of water form two natural safety-valves to the boiler, and entirely forbid any pressure within it beyond that due by gravity to their height, so that there is no more pressure within the boiler when the fire is burning, however brightly, than when the water is quite cold. It will readily be seen, however, that if the thoroughfare through the two connecting pipes were at any time to become closed, the conditions would be altogether altered, and, the steam having no longer any outlet, the pressure would inevitably accumulate within the pipes and boiler. This is just what takes place on the occurrence of a frost. The circulating pipes become choked with ice, when the pressure is bottled up within the boiler, so that if the fire burns brightly enough to raise the pressure to the ultimate strength of the plates, explosion must necessarily ensue, and the more hot water contained in the boiler, the greater its force. These explosions, therefore, are attrib-

ted simply to excessive pressure, and to prevent this is recommended that every boiler should have fixed to a metallic safety-valve, which, being unaffected by changes of temperature, would come to the rescue when clogged the other outlets. It may be added that should the water supply at any time run short, whether from frost or from being suddenly cut off by the water company, it might be well to withdraw the fire before the boiler can be run dry and overheated, not that it is thought that such serious consequences would result from the sudden re-introduction of the water, as it is very generally supposed, but the boiler, if heated, might be seriously strained and injured, although it is questioned if it would be destroyed. It may easily be ascertained whether the boiler is supplied with water or not, by opening a test tap on the circulating pipes.

Commerce.

BEST SUGAR IN THE UNITED STATES.—It appears by a New York paper that the cultivation of the beet for sugar purposes in the United States has been commenced at Chatsworth, in Livingston County, Illinois. The company which took the matter in hand planted 400 acres, mostly fresh prairie, and raised a crop of 4,000 tons of new beet, at a cost of 4 dollars a ton in the pits. The varieties were the white Silesian and the Imperial, and upon a test of various parts of the crop the average yield of fair refining sugar was found to be $7\frac{1}{2}$ per cent., and this was afterwards confirmed by analysis made at Belcher's sugar refinery, St. Louis. A number of barrels have been made, and the works are now in operation and when all the roots are worked up, the yield must reach nearly 400,000 lbs. of refined sugar. There is always delay in starting new works and machinery, and this delay has been of use in settling the question whether beetroot can be kept in America during the autumn and winter. It is found that the loss during the four months was only 1 per cent., and the conclusion of his vast experiment is, that beetroot can be grown on the raw but rich soil of the West, as well as on the highly fertilised soils of Belgium and France; that the yield of sugar is almost precisely the same, and that the roots can be kept till they are wanted. The importance of these facts can scarcely be over-estimated, for the prairie region is equal in extent to England, France, Spain, and Portugal combined, and on almost every acre the beet can be cultivated; while underlying the soil are inexhaustible beds of coal, and the Western people are fully competent to enter upon this new enterprise with energy. A beet sugar crop on these prairies will be of greater value than the corn crop, so that the importance of the successful issue of this experiment cannot be overrated. England and the United States were the only two great consuming countries of cane sugar left in the temperate zone, the continent of Europe being almost entirely supplied by the beet. A sixth part of England's consumption last year was drawn from the beet, and although she has not yet made sugar from it, the plant grows luxuriantly throughout the land. The supremacy of cane sugar in the States is now threatened, and it is perfectly evident that the only hope of cane planters is in improved machinery, and not in vain hopes of higher prices. With proper machinery and cultivation they need have no fear, but these neglected conditions are now essentials.

Colonies.

STATISTICS OF NOVA SCOTIA.—The following information has been kindly forwarded by a correspondent:—The area of Nova Scotia comprises 13,630,237 acres, of which 6,214,944 have been granted, while 7,315,293 are in the hands of the Crown. About one-fifth of the latter quantity is supposed to be fit for cultivation.

The population is estimated at 370,560. The annual death-rate is 20 in 1,000. Of the deaths registered in 1866, the causes are thus specified in the following cases:—Tubercular consumption, 22 per cent.; old age, 8 per cent.; diphtheria, diarrhoea and dysentery, typhus and infantile fevers, 4 per cent. each. Eighteen out of 100 deaths were beyond the 70th, and nine out of 100 beyond the 80th year. There were five suicides last year, and four murders. The cases of violent death amounted to 181, 76 of which occurred by drowning. The revenue for the year ending Sept. 30, 1866, was 2,080,180 dollars; the expenditure, 1,961,840 dollars. The imports of the year amounted to 14,381,008 dollars; the exports to 8,043,095 dols. Principal items of export:—Horned cattle, 4,339; sheep and lambs, 10,142; butter and lard, 723,167 lbs.; cheese, 17,404 lbs.; coal, 399,709 tons; codfish, 33,561,284 lbs.; scalefish, 5,114,984 lbs.; herrings, &c., 154,560 barrels; mackerel and shad, 100,385 barrels; apples, pears, &c., 19,203 barrels; gypsum, lime, and plaster, 74,892 tons; fish-oil, 192,187 gallons; vegetables, 2,172,450 bushels; boards (plank), 56,832,725 feet; firewood and lathwood, 39,482 cords; laths and palings, 801,800; shingles, 14,058,450; staves, hoops, &c., 3,966,114. The number of registered vessels is 3,509; tonnage, 400,895 tons. The number of tons of coals raised during the year was 684,685, the royalty on which amounted to 52,840 dollars. The gold mines produced 24,162 ounces of gold, value 483,240 dollars. The number of passengers conveyed on the railways was 149,533. There are two lines of railway open, from Halifax to West River, 81 miles, which will be completed to Pictou, 19 miles further, shortly, and from Halifax to Windsor, 45 miles. Another line, from Windsor to Annapolis, 80 miles, is commenced. The total number of letters mailed last year was 4,863,845; number of newspapers, 5,390,155. The greatest degree of heat at Halifax was 87.5; the greatest degree of cold, 15.7. Eight years ago the Provincial Hospital for the Insane was opened; number of patients admitted, 417; recovered, 154; relieved, 38; unimproved, 15; died 53; remaining, December 31st last, 157.

VICTORIAN FINANCE.—The treasurer has been able to state that though the revenue for 1866 had fallen considerably below his expectations, the savings on the votes of the year had been proportionately large. The total receipts were \$3,322,887, a sum which met the expenditure, and left a balance of £1,108 to be carried to the service of 1867. He estimated the total revenue for the current year at \$3,380,186, and the expenditure at \$3,379,078, leaving a surplus of only \$242. The estimates contain a great variety of works, but not any of great importance. The Treasurer put it to Parliament, however, that it was better to meet this large expenditure by fresh taxation, than to postpone useful public works. The additional revenue necessary to meet this large public expenditure he proposed to raise by an increase in the duties upon imports, and by adding to the list of dutiable goods many articles hitherto exempt.

Obituary.

SIR ROBERT SMIRKE, R.A., a distinguished architect, died on Thursday, the 18th instant, at the age of 87. His father was an eminent artist, who, in his day, enjoyed a considerable reputation as a historical painter, and his two sons, Robert and Sydney, both obtained high distinction as architects. Robert studied for some time in the office of Sir John Soane, and subsequently spent several years in Italy, Sicily, and Greece. He was elected a Royal Academician in 1813, and in 1823 was entrusted with the building of the British Museum, and shortly after with the new Post-Office; these, and the restoration of York Minster after its destruction by fire, in 1829, being among the best known of his public works; Lowther and Eastnor Castles are among the best

specimens of private mansions built by him. Having been many years architect to the old Board of Works, he was knighted in recognition of his services, when, in 1831, that Board was reconstituted. For a short time he held the office of treasurer to the Royal Academy, but relinquished that appointment on going to reside at Cheltenham in 1850; and a few years ago, finding his declining health materially interfering with the efficient discharge of the duties of a Royal Academician, he resigned its honours that they might be conferred upon a younger and more active man. Sir Robert Smirke, in 1819, married a daughter of the Rev. A. Freston, rector of Edgeworth, in Gloucestershire.

MEETINGS FOR THE ENSUING WEEK.

- MON.....** R. United Service Inst., 84. Commander P. H. Colomb, R.N., "Lessons from Lissa."
British Architects, 8.
Actuaries, 7. Mr. W. M. Makeham, "On the Law of Mortality."
Medical, 8.
Asiatic, 3.
Social Science Assoc., 8. General Meeting of Health Department.
Philosophical Club, 6. Annual Meeting.
TUES... Royal Inst., 3. Prof. Blackie, "Plato."
Antiquaries, 2. Annual Meeting.
Civil Engineers, 8. Discussion upon Colonel Sir William Denison's paper on "The Suez Canal;" and, time permitting, Mr. James T. Chance, "On Optical Apparatus used in Lighthouses."
Anthropological, 8.

Journal of the Society of Arts.

FRIDAY, MAY 3, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

MAY 8.—“On the Recent Inventions and Improvements in European and American Breech-loading Small-arms.” By Capt. O’HEA, late 25th Regt. K.O.B.

MAY 15.—“On New Machinery for Cutting, Tunneling, Quarrying, and Facing Slate, Stone, and Marbles.” By W. FOTHERGILL COOKE, Esq.

CANTOR LECTURES.

The concluding lecture of Mr. HULLAH’s course, “On Music and Musical Instruments,” will be delivered as follows:—

LECTURE VIII.—MONDAY, MAY 6.

MODERN INSTRUMENTS, CHAMBER AND ORCHESTRAL.—The Pianoforte—Combination of Instruments—The Orchestra.

The concluding lectures of Mr. CHAFFERS’ course, “On Pottery and Porcelain,” will be delivered as follows:—

LECTURE VI.—MONDAY, MAY 13TH.

ENGLISH POTTERY.—Fulham—Lambeth—Yorkshire—Shropshire—Liverpool—Staffordshire—Etruria—Wedgwood’s Wares, &c.

LECTURE VII.—MONDAY, MAY 20TH.

ENGLISH PORCELAIN.—Bow—Chelsea—Derby—Worcester—Liverpool—Wales—Plymouth—Bristol—Lowestoft—and other Manufactories—Battersea Enamel, &c.

The lectures commence at eight o’clock, and are open to members, each of whom has the privilege of introducing one friend.

CONVERSAZIONE.

The Council have arranged for a Conversazione on Thursday evening, the 23rd May, at the South Kensington Museum, cards for which will shortly be issued.

ARTIZANS’ VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object. The following gentlemen constitute the Committee:—

Rt. Hon. C. B. Adderley, M.P.	A. S. Ayrton, M.P.
C. W. Aitken.	S. A. Beaumont.
Edward Akroyd, M.P., Vice-Pres.	John Bell, <i>Memb. of Council.</i>
Sir Wm. G. Armstrong, C.B.	Professor Bentley, <i>Memb. of Council.</i>
	Lord Berners, <i>Vice-Pres.</i>
	Hon. and Rev. S. Best.

D. Robertson Blaine, <i>Memb. of Council.</i>	Hon. A. F. Kinnaird, M.P.
W. H. Bodkin (Assistant-Judge), <i>Vice-Pres.</i>	Lord Henry G. Lennox, M.P., <i>Vice-Pres.</i>
Sir J. P. Boileau, Bart., <i>Vice-Pres.</i>	The Bishop of London.
R. K. Bowley.	The Sheriffs of London and Middlesex.
Antonio Brady.	Rt. Hon. Robt. Lowe, M.P.
Rt. Hon. H. A. Bruce, M.P.	Lord Lyttelton, <i>Vice-Pres.</i>
Decimus Burton.	Archbishop Manning.
C. Buxton, M.P.	Henry Maudslay, <i>Memb. of Council.</i>
The Earl of Caithness, <i>Vice-Pres.</i>	Rev. F. D. Maurice.
Lord Eustace Cecil, M.P.	The Lord Mayor.
R. L. Chance.	J. Stuart Mill, M.P.
Harry Chester, <i>Vice-Pres.</i>	Rev. Dr. Miller.
The Masters of the City Companies.	The Bishop of Oxford.
Henry Cole, C.B., <i>Vice-Pres.</i>	J. Slaney Pakington, <i>Memb. of Council.</i>
Robt. Coningsby.	Right Hon. Sir John S. Pakington, Bart., M.P., <i>Vice-Pres.</i>
Rt. Hon. W. Cowper, M.P.	Alderman Sir B. S. Phillips.
Sir Francis Crossley, Bart., M.P.	Sir Thomas Phillips, Q.C., F.G.S., <i>Vice-Pres., Chairman of the Council.</i>
J. Bailey Denton, <i>Memb. of Council.</i>	The Duke of Richmond.
Lord de l’Isle and Dudley, <i>Vice-Pres.</i>	Rev. W. Rogers.
The Duke of Devonshire.	The Marquis of Salisbury, K.G., <i>Vice-Pres.</i>
Charles Dickens.	Titus Salt.
James Easton, <i>Memb. of Council.</i>	Sir Francis Sandford, <i>Vice-Pres.</i>
C. W. Eborall.	Colonel Scott, R.E., <i>Memb. of Council.</i>
Lord Ebury.	The Earl of Shaftesbury.
Lord Elcho, M.P.	Benjamin Shaw, <i>Memb. of Council.</i>
William Fairbairn, F.R.S.	Sir J. P. Kay Shuttleworth, Bart., <i>Vice-Pres.</i>
Professor Fawcett, M.P.	S. Smiles.
Peter Graham, <i>Memb. of Council.</i>	Seymour Teulon, <i>Treasurer.</i>
The Earl Granville, K.G., F.R.S., <i>Vice-Pres.</i>	Thomas Twining, <i>Vice-Pres.</i>
The Earl Grosvenor.	Alderman Waterlow, <i>Memb. of Council.</i>
Mr. Hansard.	E. W. Watkin, M.P.
G. W. Hastings.	G. Watts.
Wm. Hawes, F.G.S., <i>Vice-Pres.</i>	George F. Wilson, F.R.S., <i>Memb. of Council.</i>
J. Pope Hennessy.	Vice-Chancellor Sir Wm. Page Wood, F.R.S., <i>Vice-Pres.</i>
Sir Rowland Hill, K.C.B.	
Chandos Wren Hoskyns, <i>Vice-Pres.</i>	
T. Hughes, M.P.	
Blanchard Jerrold.	
Rev. O. Kingsley.	

The Council, on the recommendation of the Committee, have passed the following minute:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government to facilitate the visits of skilled artisans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

The following report has been made by the Secretary:—

To the Council of the Society for the Encouragement of Arts, Manufactures, and Commerce.

GENTLEMEN,—In compliance with the directions of the Council, I proceeded to Paris for the purpose of ascertaining what arrangements were likely to be available with regard to the lodging and boarding of such artizans as might visit Paris under the auspices of the Society.

I soon found, from inquiries made in various quarters, that little information of any value, as to the probable cost of private lodgings generally, or as to what lodgings would probably be available, was likely to be obtained; indeed, any figures or statements under this head at that time were not likely to be of any use, or in any way to be a guide to the deliberations of the Committee.

The prices asked at that time were exceptionally high, but there was every reason to believe that a reaction would take place, and that, after the exhibition had been open a short time, these prices would diminish.

Mr. Cook, the well-known excursionist, I found was prepared to contract for the lodging and boarding of 50 artizans per week, supplying two substantial meat meals per diem, for 6s. per head per day. I subsequently placed myself in communication with M. Le Play, the General Commissioner of the Exhibition, who informed me that a Special Commission had been formed, under a ministerial decree, for effecting the very objects I was in search of, and he gave me a special letter of introduction to the Chairman of that Commission, Mons. Devinck, formerly President of the Tribunal of Commerce for the Department of the Seine, and I had two interviews with that gentleman. It appears that the object of this Commission is to raise, by subscription or otherwise, funds for facilitating the visits to the exhibition of foremen, workmen, or labourers connected with industrial and agricultural pursuits, and for enabling them to study the exhibition in all its aspects.

The Commission proposes to raise a fund (to which the Emperor and Empress have subscribed largely) in order to provide lodging and board at a cheap rate for artizans, to assist workpeople in their travelling to and from Paris, and to supply gratuitously medical aid in case of sickness. Mons. Devinck informed me that the Commission expected to have under their control five thousand beds. These are situated in different parts of Paris and the outskirts. They have had placed at their disposal large buildings and barracks, and some of a temporary cha-

racter have been specially erected in the neighbourhood of the exhibition, which will be furnished suitably for the purpose, and beds will be arranged in the rooms four and upwards in each room. In one of the buildings it is said that several hundred beds will be placed in one room.

Arrangements are made for breakfasts and dinner on a large scale and at a cheap rate, in a building erected for the purpose, with access to the Champ de Mars, where 1,000 persons can take refreshments at one time.

These arrangements, more especially those for aiding workmen gratuitously in their travelling expenses, were intended for French workmen, but at the same time the organisation of the Commission is intended to be available for the workmen of other countries.

It is also intended that guides, speaking English and such other languages as may be necessary, shall be provided to conduct the men over such workshops as they may wish to visit. M. Devinck stated that on receiving notice a sufficient time beforehand, the Commission would be prepared to provide lodging for such men as might be sent over and recommended to their consideration by the Society of Arts, at a payment of one franc per night per head. Their breakfasts—a substantial meal of meat—and dinners would be obtainable in the building I have before named, at one franc per head for each meal.—I am, &c.,

P. LE NEVE FOSTER, Secretary.

P.S.—Since writing the above, I have received the following tariff of prices at the restaurant referred to in my letter:—

GRAND RESTAURANT OMNIBUS, PARC DE L'EXPOSITION (AVENUE LAMOTTE-PIQUET).

Prix des objets de consommation.

	Ofr.	10c.
Pain	0	15
Vin, le carafon	0	25
Bière, la chope	0	15
Bouillon	0	20
Potage	0	25
Bœuf	0	20
Légumes	0	15
Fromage	0	30
Café avec eau-de-vie	0	40
Roti avec légumes	0	40

On peut demander un seul des objets de consommation ci-dessus mentionnés.

Le consommateur, en apportant son pain, peut se procurer pour 0fr. 40c. l'ordinaire (bouillon et bœuf).

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

The Council have received offers of co-operation from a Committee for promoting cheap excursions to the Exhibition, formed under the auspices of the "Working Men's Club and Institute Union," and of which Mr. A. H. Layard, M.P., is President, and Mr. Hodgson Pratt, Vice-President. This Committee has issued a notice to the effect that working-men may travel "to Paris and back, with one week's lodging," for 30s., or "with meat breakfast and superior bed accommodation," 44s. 6d. They estimate the total expense of stay (for one week), journey, and Exhibition ticket, at £3. Registration tickets, and every information relative to these excursions may be obtained from the Secretary, Mr. W. O. Pocklington, at 150, Strand, and at various Working Men's Clubs and Institutes.

HARVESTING OF CORN IN WET WEATHER.

The Council of the Society of Arts have resolved to offer the Gold Medal of the Society, and a Prize of Fifty Guineas, for the best Essay on the Harvesting of Corn in Wet Seasons.

The first part of such essay—after noticing the various systems at present adopted in damp climates for counteracting the effects of moisture upon cut corn in the field, and for avoiding such exposure in wet seasons by peculiar harvesting processes—should furnish a practical and analytic exposition of the best available means:—

- 1st. Whereby cut corn may be protected from rain in the field.
- 2nd. Whereby standing corn may, in wet seasons, be cut and carried, for drying by artificial process.
- 3rd. Whereby corn so harvested may be dried by means of ventilation, hot air, or other methods; with suggestions for the storage both in the ear and after threshing.
- 4th. Whereby corn, sprouted, or otherwise injured, by wet, may be best treated for grinding or feeding purposes.

The whole to be supplemented by a statement of practical results, and actual cost of each system described; and authenticated estimates of any process proposed for adoption, based upon existing but incomplete experiments.

The above requisitions are given suggestively; not to bind the writer to the order or to limit the treatment of the subject, provided it be kept within the scope of practical experience and utility.

The essays must be sent in to the Secretary of the Society of Arts on or before the 1st of January, 1868.

The Council reserve the power to withhold the whole or part of the prize, in the event of no essay being, in the opinion of the judges, of sufficient merit.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Cutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

A meeting of the Sub-Committee on Meat was held on the 3rd ult., at which there were present—The Right Hon. Henry Austin Bruce, M.P., in the chair; Mr. Clare S. Read, M.P., Mr. Benjamin Shaw, Mr. Michael, Mr. J. Ludford White, Mr. Jas. Ware, Professor John Wilson, and Mr. E. Wilson.

Dr. ALFRED S. TAYLOR attended the Committee, on the invitation of Mr. Benjamin Shaw, and he brought for the inspection of the Committee a tin case of preserved provisions which had formed part of the stores of H.M.S. *Blonde*, in the year 1826. The tin was opened in the presence of the Committee. An account of its condition, drawn up by Dr. Taylor, will be found at the conclusion of his evidence.

Dr. TAYLOR, in reply to inquiries put by the Committee, stated he was not aware of the precise method by which this specimen of provisions just opened had been preserved. It had no doubt been preserved by raising the meat in the tin to a somewhat high temperature, obtained by immersing the tin in a bath of boiling brine, and hermetically sealing the tin by means of solder whilst the steam was rushing out, and thus preserving the contents in vacuo. The process was the same as that now in use, though probably not effected at that time with the same care which is now used. The necessity for the perfect exclusion of air from the meat was shown in the instance before them by the rapidly oxidising effects of the air upon the contents of the tin. In a few hours decomposition would take place. Allowance, however, was to be made for the extreme length of time that had elapsed. There were certain points to which attention must be paid in connection with the artificial preservation of meat. His investigations had been directed in the first instance to the circumstances connected with the decomposition of animal substances and the best means of preserving meat for the purpose of food. Putrefaction of animal and nitrogenous principles used as food resulted from three primary causes, viz., 1st, air, by supplying oxygen; 2nd, water, or moisture; 3rd, a temperature above 60°. These were the three main conditions. All that need be done in preserving animal matter was to find out which of these conditions could be completely suppressed or put aside. With regard to air, putrefaction was arrested by heating the substance in close vessels, and the exhaustion of the air would be facilitated by the vacuum process by heating at a low temperature, as was done by vacuum pans in the manufacture of sugar. Putrefaction was also arrested in animal substances by gases or vapours which contained no free oxygen—such as nitrogen, carbonic acid, and chloroform, or by the use of gases which combine with and remove free oxygen, such as deutoxide of nitrogen (nitric oxide) and sulphurous acid. The latter, being very soluble, is liable to be absorbed by the flesh, and to act chemically upon the colouring matter, taste, &c. He had tried various experiments in the preservation of slices of beef in nitric oxide, which was very effectual in preventing putrefaction. In the first experiment he kept the meat for eighteen weeks, in a second for nineteen weeks, in a third for thirty-two weeks, and in a fourth for eighteen months, from October 27th, 1862, to March, 1864. During these periods the flesh was exposed to two of the conditions of putrefaction, viz., moisture and high temperature. The summer was very warm. This gas is remarkable in this respect, it will not allow free oxygen to come into contact with it. At the end of the eighteen months the meat retained its red colour and appearance, although it was exposed during the whole time to the varying temperatures of the laboratory. The simple abstraction of the oxygen was sufficient to preserve the meat completely. This process, although not practically applicable for preserving food, was useful in showing that oxygen is the main agent of destruction. Keep that away, and the other two conditions are of no importance. That applied to the preservation of food in tins, from which air was excluded by exhaustion by heat, and also to Redwood's process, in which the substance was imbedded in paraffine. In the latter case the meat was preserved like the flesh of the Egyptian mummies, and the material in which it was enclosed got into the flesh and excluded the oxygen. Then, with regard to moisture. If the water were taken away from the most putrescible matter it could be preserved for a long time. Dr. Taylor produced a specimen of white of egg from which the moisture had been removed in a vacuum, by the aid of dry chloride of calcium. In that way he said the albumen was dried to the gummy matter now presented, forming about one-fifth of the original albumen; but with the addition of four parts of water it could be restored to its original state again. This proved that substances which would putrefy in warm weather in

twenty-four hours, yet if the water were taken away, although there were the conditions of oxygen and high temperature, they would undergo no change. Desiccation might be mentioned as another means resorted to in the preservation of food, as was seen in the instance of the tongues imported into this country from Archangel and other parts of Russia. These were slightly salted, and smoked by being suspended in chimnies over wood fires, and so thoroughly desiccated that they would remain good in warm or cold climates for almost any length of time. Dr. Taylor placed a specimen of a dried Russian tongue before the Committee, and explained that an ox tongue could be detected from that of a horse by the difference in the form of the epiglottis of the two animals. When the epiglottis remained on the tongue it might be inferred whether it was that of an ox or a horse, while the removal of that portion from the tongues imported into this country might create a suspicion that they were the tongues of other animals than the ox. These tongues, Dr. Taylor explained, on being soaked in water for twenty-four or thirty-six hours, regained very nearly the original quantity of moisture of which they had been deprived by desiccation. He learnt from his friend beside him (Dr. Gwosdew, of Moscow, a Russian physician) that with a temperature below 40°, although oxygen and moisture were present in the substance, there was no tendency to decomposition, so that meat buried in the soil below 40° might be kept good for months. This plan was resorted to for preserving provisions in the Arctic expeditions. The provisions were buried in the frozen earth, the positions being indicated by stones placed over them, and after many months they were found to have undergone no change. Dr. Taylor then went on to state the principles to be observed in the preservation of animal food. These were—

1. No chemical compound to be used, with the exception of salt, and that only in small quantity.

He thought the use of salted meat, in the way it was ordinarily understood, was not desirable, because it hardened the meat, and rendered it more or less indigestible, and there were no means by which the chemist could get the salt out again. Salt in large quantity added to the insolubility of the meat. A small quantity of salt was beneficial in the preservation of food, as chloride of sodium added to the other principles tended to prevent the growth of fungi. The next point was—

2. The fleshy portion, drained of blood, to be selected; only those portions to be taken which are in a sound state, and as soon after death and cooling of the body as possible.

The draining away of the blood was a point of great importance, because there was no portion of the body so prone to decomposition as the blood; hence, butchers were careful to drain the blood from the animals they slaughtered as much as possible. It was therefore desirable that the portions of flesh intended for preservation should be entirely free from blood, on account of the albumen it contained, which was easily decomposed. One of the first effects of decomposition was mustiness, which spoils the taste of food—so that in getting rid of the blood we get rid of matter which was most prone to decomposition. On the point of selecting only those portions which are in a sound state, he would remark that in many instances, there could be no doubt, bad consequences had resulted from placing unsound meat with the sound. It was well known that when animal matter affected by decomposition was placed in contact with fresh matter, it tended to set up decomposition throughout the whole mass. That was a most essential point, which should be considered by those by whom the food was prepared. On the point of the preparation of the flesh as soon after death and cooling of the body as possible—this was desirable on account of animalcula setting up changes

in the body which tended to putrefaction. It was therefore desirable that the meat should be preserved as soon after the cooling as possible, to prevent any incipient stage of putrefaction. Microscopic observation detected those incipient changes on the mucous surfaces of the flesh, and that threw light upon the necessity of allowing this change to begin. The next point was—

3. The portions selected to be partially cooked if heated to about 170° for a short time, in order to coagulate the liquid albumen.

In the case of some of the artificially preserved meat now in use, Dr. Taylor observed that they were subjected to a temperature of 220° or 240°; that, he believed, was the case in Redwood's process. By that means the meat might be said to be overcooked for the purpose of food. In order to preserve meat for food it was important that the original properties of the meat should be retained as much as possible. The primary object was not to cook the meat entirely, but merely to preserve it. He suggested the heat of 170°, for this reason, that the albumen, which was the most easily decomposable principle in the flesh, was solidified at that temperature without destroying the properties of the meat. He submitted that the temperature which would fix the liquid albumen viz., 170°, was sufficient for preservative purposes, and the fibrine and gelatine were at the same time retained unchanged. The time during which the meat should be subjected to a temperature of over 170° should be regulated according to the size of the joint, but the temperature should not be raised beyond that. When meat was exposed to a heat of 240° for half or three-quarters of an hour, it necessarily followed that the fibrine was hardened or corrugated, and the meat was brought to a condition less easy of digestion, as well as forming a less palatable food. In making hashes and mince of meat, if it was allowed to boil at a high temperature for an hour or two, the meat was converted into a hard fibrous material, which was very indigestible, whereas if it had been maintained at a temperature of not more than about 170°, at a slow simmer, the meat was soft and good. He thought even the temperature of 210° was too high in such cases. Meat preserved at a temperature of 170° or 180°, could be cooked to completion when required, with the addition of a little salt. Meat exposed for any considerable length of time to a temperature of 220° or 240° must be considered as overcooked. The inside of a mutton chop or beef steak was broiled underdone, and in which all the juices of the meat were retained, did not reach the temperature of 170°, but only reached that point at which the liquid albumen contained in the flesh were coagulated. He considered it preferable to subject the meat to be preserved to the lower temperature of 170° for a long period, rather than to the high temperature of 240° for a very short time. With regard to the next point, he said—

4. The meat to be introduced into tins in the usual way, and the whole of the air excluded by partial exhaustion or by heat. The absence of any free oxygen is an essential point.

It occurred to him that the exhaustion of air from the tins might be effected in a very satisfactory manner by the use of vacuum pans, like those employed in the manufacture of sugar, invented by Howard, consisting of two large copper pans in which complete exhaustion was effected. Exhaustion by the air pump could not produce more complete results than was done in reference to the tin case of preserved provisions of 1826, by heating alone. Looking to the large component part which the flesh of animals forms in the food of this country, it occurred to him as a further point—

5. The tongue and heart drained of blood and laid open, and the liver sliced and drained of blood, might be preserved by slight salting, heating to 170°, and then perfect desiccation by drawing over these parts a current of warm air.

these portions of the viscera of animals readily admitted perfect desiccation, and in that state might be sent to a country from very long distances, and would form an excellent and nutritious article of food. The only thing with regard to the liver was that it contained fatty matter which, in the process of drying, would exude, and probably give a disagreeable appearance to the surface. He had preserved portions of the human liver for years in his laboratory by thorough desiccation. In this mode of preserving food he apprehended the packing in air-tight vessels would not be required. He believed the partial cooking of the meat at the temperature of 170° would to a great extent exude the air; but he would add exhaustion as a completing process. At the next point he would submit was—

6. Either by the entire removal of oxygen, or the entire removal of moisture, the tendency to putrefaction is destroyed and the food is preserved. The desiccated food may have its properties restored by immersion in salt and water for one or two days.

At this point, he said, was sufficiently illustrated in the case of soaking dried tongues in water previous to cooking.

7. The process of desiccation will not answer for fat meats, as the fat will appear as oil upon the surface. It may not answer for the sliced liver, but this should be made the subject of experiment.

The membranous portions of fat were apt to become acid from the albumen becoming decomposed, and produced mustiness. This gave rise to the mustiness that was found in stale suet. There was no objection to it free from membrane, but it was not desirable to preserve the fat of the heart and tongue. In travelling in Italy he recollected that an excellent dish, consisting of sheep's hearts stuffed with savoury herbs, &c., was frequently served in the Italian restaurants. It was good and digestible food, as the fibres of the heart were less tough than those of the other muscles of the body. The concluding point he submitted was—

8. In preserving meats it will be desirable to remove as much as possible the blood and also the fat, and to take care that a heat of 170° is attained and not exceeded. The parts only of healthy animals to be selected.

These leading principles in the preservation of food, Dr. Taylor remarked, would, he hoped, be some little help to the Committee in the consideration of this subject.

The CHAIRMAN asked Dr. Taylor whether he considered these principles had been more or less disregarded in the methods of preservation hitherto employed.

Dr. TAYLOR replied that he had not given much attention to the examining of tins of preserved food, but from general scientific knowledge he should say they had been to some extent disregarded. He thought it probable that sufficient care had not been exercised with regard to putting unsound meat with sound; and there was reason to believe that was the case in some of the provisions supplied to the army during the Crimean war, by which the whole contents of the cases were spoiled. It was also to be apprehended that proper means were not always taken to exclude air. The test of complete exhaustion of air was the indentation of the top and bottom of the tin, while the undue convexity of the tin was an indication of the presence of gases generated by decomposition of the animal substance within the tins.

Mr. SHAW, in reference to Dr. Taylor's suggestion that the meat should be prepared at a low temperature, inquired whether he thought Tindal's system was defective in regard to the high temperature employed in his process?

Dr. TAYLOR replied in the affirmative. The meat was overcooked in the first instance. The object should be to apply no more heat than would suffice for the preservation, and afterwards to apply the cooking. He had no doubt the high temperature employed in Tindal's process was adopted from a belief that it was necessary

for the preservation of the food, and from the fact not being generally known that the albumen in meat was coagulated at a temperature of 170° . The excessive temperature of 220° or 240° consolidated the albumen to an extent which made it indigestible. Dr. Taylor did not think that experiments upon Tindal's meat, or other meats preserved in the same way, could be satisfactorily tried by artificial digestion with pepsine, or by giving it to animals and examining the results. If the pepsine, for instance, were taken from the stomach of a sheep, he should object to that being taken at all, the digestive principle of a herbivorous animal differing very greatly from that of a carnivorous animal. There was no doubt that the stomach of a dog would digest the meat with the greatest ease. If the experiment could be tried on human beings it would be preferable. Experiments, however, of a comparative character might be tried, one with the albumen coagulated at the temperature of 170° , and another when it was coagulated at a much higher degree of temperature. It was surprising what the effect was of boiling a piece of beef at a high temperature for a long time; it became hard and fibrous. He did not say it was wholly indigestible by the human stomach, but it was not by far so digestible as meat heated and cooked at a much lower temperature. The object was to obtain that which would suit the stomachs of 99 people out of 100, and in that view he was of opinion that the high temperature employed in Tindal's process was not only unnecessary, but prejudicial to the nutritive properties of the food.

The CHAIRMAN asked if a different amount of cooking would be required in meat partially cooked as Dr. Taylor had described.

Dr. TAYLOR replied it would be in the condition of a joint of meat which was partly cooked on Saturday to keep it good till Monday, when the process of cooking was completed. It would be treated as partially cooked meat. A certain amount of cooking was necessary at the place where the preparation of the meat was carried on—say Australia or South America—but he submitted that an excessive amount of cooking was unnecessary. Tindal's meat was thoroughly cooked, and required to be eaten cold as taken from the tins. Any further heating or cooking on its arrival in this country, he apprehended, would materially affect its flavour and act prejudicially on its nutritive properties, and frequently re-cooked food does not suit the stomach. The partially cooked food he recommended would obviate that. He believed a temperature of 170° entirely excluded air, and the meat was not injured either in its flavour or preservative qualities. Food so prepared would keep good for two or three years. The want of flavour which characterised the meat which he tasted at Mr. Shaw's house was very apparent. It occurred to him that in Tindal's process some of the savoury matters of the meat were volatilised, which probably might be retained at a lower temperature. The effect of excessive boiling or heating of meat to a high temperature had a most prejudicial effect in driving out the nutritive properties and retaining only the indigestible muscle and insoluble fibre of the flesh.

Professor WILSON suggested that if the temperature were not carried above the point of evaporation, or 212° degrees, there would not be so perfect a vacuum as if the atmosphere were replaced by an atmosphere of steam.

Dr. TAYLOR said no doubt that would be so, but the 170° degrees might be continued for some time without prejudicing the quality of the meat, and the cooking could be completed when it was required for use. That, he thought, would, in a great measure, meet the objection which had been stated by a member of the Committee against the present form of the Australian food. If the system were carried out on a large scale, it would be advisable, in order to exhaust the air from the tins, to adopt the vacuum-pan as used in the manufacture of

sugar, as by this means a vacuum would be obtained without heating to 212 degrees.

The CHAIRMAN asked Dr. Taylor whether he thought there were advantages in the system of preparation he recommended, as compared with sending the meat, if it were possible to do so, to this country, as fresh meat, wholly uncooked?

Dr. TAYLOR replied he was inclined to rely upon the plan he suggested rather than upon the hope of importing the meat in an uncooked and fresh state. The only means of preserving meat in a raw state was either by the application of chloride of sodium or chemical gases, and in the use of the latter agents there would be great popular prejudices, however innocuous the gases might be. There was an objection to the use of gases which were soluble in water, for this purpose. The other points on which he had prepared information to lay before the Committee, were as to the results of experiments in the drying of meats. The lean of beef contained 69 per cent. of water, and only 31 per cent. of dry solids; the average might be taken as 66 per cent. of water in the meat of beef. In drying these meats they might get rid of the whole of the water except a little which might hang about the tissues. He doubted whether they could get it all back again, but if they did so to an extent so as to make the meat soft, that was all they need look to practically. In the instance of a dried tongue, if instead of getting back the 66 per cent. of water by soaking, they could only get back 40 or 50 per cent., still the meat was eatable in that state. With regard to oysters, it was astonishing how many a person could eat of them, because they contain an enormous proportion of water. The solid residue of an oyster was less than 20 per cent. The analysis of an oyster was as follows:—

Solid organic matter, dry	19.02
Mineral ash, chloride of sodium phosphates ..	0.87
Water	80.11
	100.00

Thus, in five oysters eaten, four would be water and only one solid. The constituents of bread were—

Water	38.5
Solid residue, starch, dextrine, and gluten ..	61.5
	100.0

In estimating the nutrient power of food the quantity of water it contained should always be borne in mind.

In reply to the inquiries of the Committee on the subject of extracts of meat,

Dr. TAYLOR stated he had made examinations of the several extracts proposed on the system of Liebig, Gillon, and Tooth. Liebig's *Extractum carnis* is a stiff paste, of yellowish brown colour, having a strong meaty odour, quite soluble in cold water, like an aqueous extract of animal matter, with a slight acid reaction. The solution is of a dark brown colour. Boiling makes it clearer. It contains no albumen or fibrin, these being insoluble in water at a high temperature. These principles are lost in the manufacture of the extract, and thus only 10th of the solid matter of flesh is obtained while 9ths are lost, so that it could scarcely be called *Extractum carnis*, that term implying "flesh." It contains only that portion of flesh which is soluble in boiling water, and this would be a principle analogous to gelatine, but Liebig disputed the presence of gelatine in his extract. The gelatinization of a decoction on cooling depends upon whether there is a certain per-centage of animal matter present; less than two per cent. would not gelatinize the food, and the gelatinous properties might also be destroyed by the process of heating in the manufacture of the article. The extract made a good soup in combination with other matters, and was well fitted for as other foods. All extracts were open to

that the greater part of the nutrient matter was really left behind; 34 lbs. of flesh, containing nearly 24 lbs. of water, yielded only 1 lb. of extract. For meat of poor quality this process was applicable, but for good meat the retention of the fibrin and albumen was desirable. The extract in question amounted to a good quality of beef tea, and was good as far as it went, but it did not supply the nutritive qualities which were required in animal food. The flesh-producing properties of food in the human body depended upon the solid constituents of meat, of which more than 80 per cent. was proved to be water. There was no process that he was aware of by which more of the nutrient properties could be obtained in the extract than was already obtained under Liebig's system. It could not be regarded as an article of food *per se*; and the price at which it was sold was prohibitory to its extensive use in this country. In respect of the substitution of vegetable albumen for that of animal albumen which was wanting in the extract, it was to be borne in mind that all vegetables contained a very large amount of water—in some cases as much as 80 to 90 per cent. Potatoes contained from 70 to 80 per cent. of water; and in regard to all kinds of food it practically came to this—what amount of solid matter did it contain? The extract of meat made a good food in combination with vegetables, but it would never take the place of solid animal food. On the subject of Gillon's *Essence of Beef*, Dr. Taylor stated that a sample, which was procured from Bell's, of Oxford-street, in August, 1866, was examined by him in March, 1867. It was, he said, quite liquid, of a pale yellow colour, with a meaty odour. It was not gelatinous; it had a slight acid reaction. It did not become coagulated on boiling, but was copiously precipitated by tannic acid; acetic acid had no effect upon it. It contained a small quantity of alkaline chloride (sodium), but no lime or sulphuric acid. It had a pleasant taste, like beef tea. When evaporated it gave off the odour of meat, without any ammonia. Some flaky matter was deposited; it darkened in colour, and left a brown residue; this residue when burnt had the smell of animal matter, and gave off nitrogen and sulphur; the ash left after burning contained much alkaline phosphate, chiefly phosphate of potash. An ounce of it by measure weighed 48 grains. It was constituted in 100 parts of:—

	In 100 parts.	In 1 lb.
Animal extractive	5.8 ..	406 gm.
Mineral ash, phosphate of potash ..	1.4 ..	96
Water	92.8 ..	6,496
	100.0	7,000

It contained about 1/10 of its weight of solid matter of a nutritious kind, or equal to about 1 oz. in 1 lb. of extract, so that a man must have a very capacious stomach to make a really nutritive meal of these extracts. Dr. Taylor added that he had brought with him analyses of infusions of black tea and coffee. The infusion of tea was that made by his servants, and pretty strong. An ounce of it by measure weighed 448 grains. On evaporation it left a brown-coloured extract, which, when heated gave off nitrogen and some sulphur, with tarry matter. In 100 parts it was thus constituted:—

	In 100 parts.	In 1 lb.
Vegetable extractive, including ash, containing nitrogen and sulphur	0.6 ..	42 gm.
Water	99.4 ..	6,956 "
	100.0	7,000 "

Thus there was of solid matter only 2.88 grains in a cup of infusion of tea.

An analysis of a strong decoction and infusion of coffee showed the constituents to be—one ounce in measure, weighing 480 grains:—

	In 100 parts.	In 1 lb.
Vegetable extractive, tannic acid, &c., &c., containing nitrogen and sulphur	3 ..	210 grs.
Water	97 ..	6,790 "
	100	7,000 "

In addition to the above, Dr. Taylor laid before the committee the following results as to loss of weight in meat cooking:—

	Boiling. Per cent.	Roasting. Per cent.	Baking. Per cent.
Beef	20.5	32	30
Mutton—Legs	20	—	—
" Shoulders ..	31	—	—
" Loins	35	—	—
" Necks	32	—	—

More was lost by roasting than boiling. In all cases, from $\frac{1}{4}$ to $\frac{1}{2}$ the weight of meat was lost by cooking.

EXAMINATION OF A TIN CASE OF PROVISIONS PRESERVED FOR FORTY-ONE YEARS.

The tin case formed part of the stores of the *Blonde*igate, which went on a voyage to the Sandwich Islands in 1826. On her return, a portion of her stores came into the possession of the late Mr. Thomas Hamlet, Jeweller, No. 1, Princess-street, Leicester-square. In 1831 he gave me two tin cases of provisions from the stock of the *Blonde*, for the purpose of a chemical examination. They remained in my laboratory at Guy's Hospital until about the year 1846, when one of them was opened before the Chemical class at the hospital. Its contents were found to be in a good state of preservation. They were partly liquid, and partly solid. Before a chemical examination could be made, the contents of the tin case were tasted by some of the Hospital attendants. The smell and taste of the more liquid portion were like those of a rich soup, and I could only make the further observation that they were slightly acid in reaction. The Hospital attendants ate the contents without being aware that they had been kept for so long a period, and, as I was informed by my late assistant, they were pronounced to be good.

The remaining tin case was kept in the laboratory, under all the variable changes of temperature, until April 3rd, 1867, and, after a lapse of *forty-one years*, it was opened in the presence of the Food Committee of the Society of Arts. The tin on the outside of the case had perished, and the rim had become rusty, and in many parts very thin. In one part at the top there was the appearance of a comparatively recent crack in the metal. No fluid had leaked out, but air may have slightly penetrated. On removing the cover, there was no ammoniacal or other offensive odour. The contents were solid, compact, and had sunk for almost an inch below the level of the case. A large portion of the upper surface, opposite the part in which there was the appearance of a crack, was covered with a layer of white and red mould. This was removed, and below it there was a thick stratum of a fatty substance, white, very soft, and without any offensive smell. The contents were turned out, and there were large masses of meat like beef, surrounded by and imbedded in the fat. When a section of it was made, the meat presented a red colour, and had a fresh appearance, but by exposure to the air it became rapidly of a brown colour. The meat had an appearance as if it had been cooked; there was no unpleasant odour, but it had lost all meaty flavour.

Within a few hours after the tin case had been opened, I made a chemical and microscopical examination of the contents. The fatty portion was soft like thin lard. It presented no membranous appearance. It had no offensive odour; it readily melted by the application of heat, and evolved ammonia. The melted fat had a well marked acid reaction. It dissolved in a strong solution of potash

when heated, evolving much ammonia, and producing a soapy liquid. The chemical properties of the fat had undergone but little change. It resembled adipocere in containing ammonia, but it differed from it in its appearance, and in being fusible at a much lower temperature. The ammonia which it contained was not sufficient to give it that soapy character which has been assigned to adipocere.

The fibre of the meat was very soft, and, by slight pressure, it was converted into a pasty mass. Under the microscope, the fibrous structure of the meat was very well marked, but the striped appearance of recent muscular fibre was not clearly distinguishable.* It retained in a very distinct form the red colouring principle of the blood (myochrome). When a portion of the red fibre was mixed with the tincture of guaiacum and peroxide of hydrogen, it speedily gave to the guaiacum resin that bright blue colour which has been described by Schönbein as one of the properties of the colouring matter of blood. Comparative experiments were made with some raw as well as boiled meat. Both of these turned the guaiacum of a blue colour (but only by contact with peroxide of hydrogen), while the cooked meat, which had been stewed for some hours, acted more slowly, and did not produce so intense a blue colouration as the fibre of the preserved meat. The oxidizing property manifested on this resin by fresh muscular fibre was thus proved to be possessed by this meat after so long a period. This showed that the myochrome or colouring matter of the blood had not been materially changed in it.

The meat, when boiled in water for some time, was not entirely dissolved, some fibre remaining. The solution, which was opaque, was slightly acid, and had a disagreeable odour. It gave off ammonia, and this was greatly increased when a small quantity of potash was added. The fibre of the meat was then entirely dissolved, forming a reddish-brown solution. When the alkaline solution was treated with oxide of lead, the dissolved fibrine was found to contain a quantity of sulphur.

The aqueous solution contained only a trace of alkaline chloride (common salt). It was copiously precipitated by tannic acid, corrosive sublimate, chloride of platinum, and sub-nitrate of mercury,—in all these respects resembling a solution of gelatine which had lost the power of setting into a jelly by cooling. Acetate of lead, and nitroprusside of sodium produced no change of colour.

The fibre was entirely dissolved by cold glacial acetic acid. This solution was precipitated by potash, and the precipitate redissolved by an excess of the alkali, in these respects resembling the fibrine of flesh, but, owing to its altered molecular state, this meat fibre was much more soluble. When a portion of the meat fibre was submitted to destructive distillation, it evolved a large quantity of ammonia and sulphur—chiefly as sulphide of ammonium. Lead paper was blackened, red litmus paper was rendered blue, and the nitro-prusside of sodium, when exposed to the vapours, acquired a rich crimson red colour.

When the contents of the tin case (meat and fat) had been enclosed in a bottle for an hour, there was an offensive smell like that of decomposing animal matter. Test papers were applied, with the appropriate tests, to detect ammonia, sulphuretted hydrogen, and phosphuretted hydrogen, but there was no indication in half an hour of any of these offensive gases escaping from the substance.

The general conclusion from this examination is, that the contents of the tin case consisted of meat and fat

* My colleague, Dr. Moxon, Professor of Pathological Anatomy in Guy's Hospital, subsequently made a more minute microscopical examination of another portion of the fibre, and he states that he found the structure most perfect. The striped markings observed in the recent fibres of the voluntary muscles were very distinctly seen. This affords another proof of the perfect preservation of the flesh after so long a period, namely, that even its microscopical characters had undergone no change.

which had probably been partially cooked but not salted, or only to a slight extent; that the fat and meat retained their chemical properties, but had undergone physical changes in a softening of their substance. These had not been sufficient, however, to affect materially the colour or the distinctly fibrous character of the meat. Small quantities of ammonia were present in the fat and fibre, but these were only indicated by the application of heat. Both had an acid reaction on test paper; this was stronger in the fat than in the lean portions. An upper layer of fat had tended to preserve the meat, and the preservation was aided by the close and compact manner in which the contents had fallen together. The growth of white and red fungi—the former apparently the *penicillium candidum*—shows that at some period, as a result of the rusting of the metallic case, air had obtained access to the contents. The white fungus was accompanied by a crop of a bright, brick-red looking fungus.

It could not be expected that the contents of a tin case, whatever process of preservation may have been used, would be fit for food after the lapse of forty years. The result, however, has a scientific interest in reference to the processes employed for the preservation of food. Out of the three conditions required for the decomposition of animal matter—namely (1), access of free oxygen (air), (2) the presence of moisture, and (3) temperature—the only one not brought into operation here was the first. There is every reason to believe that, when originally prepared, the oxygen of air had been completely excluded from the interior of this tin. There was abundant moisture in the material when opened, and, with regard to temperature, the case had been kept under all variations of summer and winter temperature over a period of forty years. No chemical substance, so far as one could judge, had been used for the preservation of the contents. The quantity of common salt was very small. The food had no doubt been partially cooked and then rapidly sealed up in a vessel made air tight. These results would point to the sufficiency of partial cooking, and the perfect exclusion of oxygen in a free state, for the preservation of the flesh of animals now wasted in South America and in some of our colonies. That mode of preservation, carefully carried out, which allowed the fibre of meat to retain most of its chemical properties for a period of forty years, will, of course, operate with efficiency for two, three, or five years, and, practically speaking, so long a period as this would scarcely be required. The destruction of the tinned iron case by oxidation on this occasion also leads to another suggestion, namely, that these cases should be coated with a thick layer of paint, or asphalt varnish; the latter would be preferable. These might be renewed when the provisions are required to be kept for a long period.—ALFRED S. TAYLOR.

April 5, 1867.

The Committee have received, through the courtesy of Lord Stanley, Her Majesty's Secretary of State for Foreign Affairs, a report drawn up by the legal adviser to her Majesty's Embassy at Paris, and addressed to Lord Cowley, relative to the provisions, action, and effect of the French laws against frauds by adulteration, or by the use of false weights and measures in the sale of food in France, together with the text of the laws themselves. These documents, of which the following are translations, were forwarded to the Committee, in reply to the letter addressed to Lord Stanley, which appeared in a recent number of the *Journal* (see page 305):—

Paris, March 7, 1867.

MY LORD,—Your Excellency has asked me what are the provisions of the French law against frauds in the

sale of provisions, whether by adulteration or by false weights or false measures. You have, moreover, desired to have explanatory details upon the action and effect of these penal regulations.

I have the honour to send you annexed:—1st. The text of Article 423 of the Code Pénal; 2nd. The text of the law of the 27th March, 1851, the special object of which is the strict check upon deceit in quality and quantity in the sale of goods. The comprehensive terms of these enactments include the punishment of all kinds of frauds. The law does not undertake to define fraud; it leaves that to the discretion of the judge, founded on the facts which come before him. Frauds are as ancient as dealings between men. The Roman law contains many very severe laws upon fraud committed in the sale of goods. The laws of the middle ages against fraud in commerce are very numerous. In our modern legislation since 1789 we find a number of repressive laws, some general, some special, such as those affecting gold stuffs, velvets, cloths, soaps, trade marks, butchers, bakers, &c.

All these laws are in force, and are often applied. In the place of these laws, Article 423 of the Code Pénal can be resorted to, which punishes, in a general manner, all deceit in quality and quantity of goods sold. The decision of the courts has stamped the character of fraud on all acts which affect the genuineness and purity of food. Thus are punished as fraudulent—mixing corn kindly and beetroot brandy with pure Cognac, and selling it under that name; the addition of water to wine and to milk; the sale, under the name of cashmere, of materials fabricated without the use of the cashmere goat; the sale of artificial mineral waters in place of natural mineral waters; or of all other pharmaceutical productions not genuine. This list might be extended without end, but it is only necessary to repeat that the courts are absolute judges as to what amounts to fraud. They take into consideration fraudulent intention, the illegality of the profit, the tricks of the sellers, and the prejudices of the buyers. It must, however, be added, that the courts have never punished certain mixtures authorised by commercial use, such as the mixture of strong with weak wines to improve the latter; the law only attacks adulterations. The mixture of sugar from the potatoe with sugar from beet root, or from the cane, is a punishable adulteration. Leeches which have been used, and which are sold as fresh, are considered in the light of adulterated goods, and so is also the sale of damaged corn, &c. Article 3 of the law of 27th March, 1851, punishes even the possession of false weights or false measures, or the adulteration of food; and if the food contains noxious substances, the penalty is greater. This provision of the law, however, is not new. It may be found in the books of the Hebrews, in the laws, and in numerous edicts of the middle ages, when all trade guilds had regulations with regard to weights and measures and the quality of the goods. The law of 27th March, 1851, includes all tricks by which the buyer does not get his full weight; thus the weighing of provisions with a very thick paper, though intended as a wrapper, is a fraud in quantity. In a word, it is necessary that the quantity should be exact, though a slight deviation is allowed, of which the court are the sole judges as to what is right, in the same way as they judge of actual frauds and attempts at frauds—for attempts at frauds are equally punishable with frauds themselves.

I will now pass on to the manner in which these penalties are determined and prosecuted, and finish with a few words on the effect of these laws. The surveillance of frauds is confided to the prefects, the sous-prefects, to the mayors, and to the deputies of these officers. It is also confided to the commissioners of police, to the verifiers of weights and measures, to the controllers of the warranty of gold and silver materials, and to the officers of revenue. All these functionaries put the law in force, under the authority of general rules, or local rules emanating from municipal autho-

rities; they make, unexpectedly, visits of inspection and verification; they have power to make domiciliary visits. When they meet with an infringement of the law they make out a written report of the case, which is forwarded to the Procureur Impérial, a magistrate charged with the prosecutions of all infractions of the law. The Procureur Impérial summons the delinquents before the police-court, which pronounces the penalty. This is a public proceeding and the duty of a public officer, but there is besides the private action, which every one can bring for damages he has suffered; it is thus that cheated buyers can summon the sellers before the police-court and claim damages for the injuries sustained, unless the Procureur Impérial has obtained them in addition to the punishment. It must not be forgotten that all the legal agents for the prosecution of offences have taken an oath to fulfil faithfully their duties, which renders their testimony worthy of credit; but there is besides the immediate seizing of all things which have aided the fraud. This seizing, which allows the Court to judge by its own tribunals the reality of the crime, is a powerful means of controlling the execution of the law by the agents. If the tribunals have not sufficient knowledge themselves to judge the offence, for example, mixing, in an article of food, strange or noxious substances disputed by the delinquent, they can order a report and require the aid of experts before giving their decision. The trial always takes place before the tribunal of the district where the offence has been committed. The delinquents can defend the prosecution by all the means in their power, such as their good faith, their ignorance, their inexperience in commercial matters, which may be considered as extenuating circumstances, as in all other criminal matters; they can also plead limitation, which is for three years, the same as for other crimes. The two penalties under this law are fine and imprisonment, the scale of which varies according to the gravity of the offence; the terms of the law in this respect are very explicit. Fine is pronounced independently of the damages and restitution which the courts have power to order. The fine is paid to the Treasury; the damages and restitution are given to the injured parties. Amongst the most efficacious penalties is that which orders the judgment to be affixed upon the walls of the street and on the delinquent's door, or the publication of the judgment in the newspapers. Judgment given in matters of fraud in goods may be appealed from by means of opposition appeal and the petition to the *Cour de Cassation* on the ground of being contrary to law. The law of 27th March, 1851, has had for its principal end the prevention of frauds in innumerable cases which occur with regard to provisions; the laws previously in force had been found insufficient in many cases; the foreign commerce of France suffered much from these frauds, which had been constantly denounced in the French Parliament; in 1849, in the single department of the Seine, comprehending Paris and the towns of St. Denis and Sceaux, there were 6,702 complaints of frauds, which were brought before the lower tribunals of police, for want of precision in the old law (article 423 of the Code Pénal), and in the absence of the law of 1851, which was made especially to protect the interests of the working classes, who are the first victims of fraud. This law was much discussed in the legislative assembly. Certain speakers feared lest a facility for such prosecutions should fetter freedom of trade, whilst it was admitted that unchecked fraud is a great embarrassment in matters of business. We do not willingly deal with those countries where fraud is common. A special law of 23rd May, 1857, has extended the provisions of the law of 1851 to drinks, and this was much required. The effect of this active repression has been, as shown by criminal statistics, that the large number of prosecutions and condemnations have led to the diminution of frauds. The following figures are given:—From 1840 to 1850 the number accused of cheating in quantity or quality of merchandise never

rose to more than 350 per annum, prosecuted under the old article 423, of the Code Pénal; in 1851 the number rose to 4,383 accused, of whom 1,028 were condemned to prison, and 2,862 were fined under the provision of the law of March 27th, 1851; in 1853 there were 7,353 accused, 1,811 of whom were condemned to prison, and 4,724 were fined; in 1858 there were 7,014 accused, 1,639 were imprisoned, and 4,742 were fined; in 1864 only 3,406 were accused, 794 were sent to prison, and 2,470 were fined—a great diminution in the number of accused. It results from these figures that the prosecutions have been very frequent, but also that from 1850 to 1864 there has been an important improvement. The agents of the law never relax in their prosecutions; there is not a week in Paris without numerous condemnations, above all in the retail trade; but, in spite of the vigilance of the authorities, frauds are still numerous, especially as regards quantity, whilst adulterations have considerably diminished. The mixture of noxious matters is especially tending to disappear. The greatest number of condemnations are found to be in additions of water to wine and milk. I hope your Excellency will not consider these explanations too long, and that they will facilitate the understanding of the dry text of the law.

I have the honour to be, &c.,

(Signed)

TRÉPITE.

To His Excellency Earl Cowley, &c., &c., Her
Britannic Majesty's Ambassador at Paris.

TEXT OF THE FRENCH LAWS AGAINST ADULTERATION AND THE SALE OF ALIMENTARY PRODUCTS BY FALSE WEIGHTS AND FALSE MEASURES.

Article 423 of the Code Pénal.

Whoever shall have deceived the buyer in matters of gold or silver, in the quality of a false stone, sold for a real one, in the quality of all goods; whoever, by use of false weights and measures, shall deceive as to the quantity of articles sold, shall be punished by three months' imprisonment at least, a year at most, a fine, which must not exceed one-fourth of the value and damage, nor be less than 50 francs. The fraudulent articles or their value, if they still remain in the possession of the seller, will be confiscated, and, moreover, destroyed.

The court can order the judgment to be posted in such places as it may name, and order its insertion in full, or an extract from it, in all the newspapers, and at the expense of the condemned.*

Special Law of 27th March, 1851.

ARTICLE 1.—The following offenders come within the terms of the above article:—

1st. Those who adulterate alimentary or medicinal substances intended for sale.

2nd. Those who sell, or who offer for sale, alimentary or medicinal substances knowing them to be adulterated.

3rd. Those who deceive, or attempt to deceive, as to quantity the persons to whom they sell or of whom they buy, by the use of false weights, or by false measures, or by false instruments, used for weighing or measuring, or by tricks or plans tending to falsify the operation of weighing or measuring, or augmenting fraudulently the weight or size of the merchandise, even before the weighing or measuring, or by fraudulent indications leading to a belief in a previous exact weight or measure.

ARTICLE II.—If in the cases provided for by Article 423 of the Code Pénal, or by Article I. of the present law, a question arise that the offence shall relate to the mixture of articles noxious to health, the fine shall be from 50 francs to 500 francs, unless the fourth of the restitutions and damages exceeds the latter sum. Im-

* This latter clause has been added only since 1863, by the law of 13th May. N.B.—The penalties pronounced by this article can be mitigated by the Court, when they find extenuating circumstances in favour of the accused; the tribunal can, in this case, reduce imprisonment to six days, or only impose a fine.

prisonment shall be from three months to two years. The present article shall even be applicable to those cases where the injurious adulteration shall be known to the buyer or consumer.

ARTICLE III.—Those who, without lawful reason, shall have in their warehouses, shops, workshops or houses of business, or in the markets or fairs, either false weights or measures or other incorrect apparatus, for weighing or measuring either alimentary or medicinal substances, knowing them to be adulterated, shall be punished by a fine of 16 francs to 25 francs, and be liable to an imprisonment of from six to ten days, or one of these penalties only, according to circumstances. If the substance adulterated be injurious to health, the fine may be increased to 50 francs and the imprisonment to fifteen days.

ARTICLE IV.—When the accused, convicted of breaking the present law, or Article 423 of the Code Pénal, shall have been, in the five years which precede the offence, condemned for breaking it before, the penalty shall be increased to double the maximum. The fine pronounced by Article 423 and by Article I. and II. of the present law, may even be raised to 1,000 francs if the half of restitution and damage does not exceed that sum. The whole of this law is to be read without prejudice to the application of Article 57 and 58 of the Code Pénal.

ARTICLE V.—The objects the sale of which, or the use or possession of which, constitute an offence, shall be confiscated, in conformity to Article 423 and to Articles 477 and 481 of the Code Pénal. If they are applicable for food or medicinal use, the Court can hand them over for the use of charitable institutions. If they are improper for use or hurtful, they will be destroyed at the expense of the condemned. The Court can order that the destruction shall take place in front of the establishment or house of the condemned.*

ARTICLE VI.—The Court can order the judgment to be affixed in places it designates, and the full insertion or mere extracts in all the journals it names, all at the expense of the condemned. (This penalty is much dreaded.)

ARTICLE VII.—Article 463 of the Code Pénal will be applicable to offenders provided for by the present law.

ARTICLE VIII.—Two-thirds of the produce of the fines are handed over to the Communes where the offences take place.†

CANTOR LECTURES.

"ON MUSIC AND MUSICAL INSTRUMENTS." By JOHN HULLAH, Esq.

LECTURE VII.—MONDAY, APRIL 29.

MUSICAL INSTRUMENTS. — (Continued.)

After briefly reminding his audience of some points in his last two lectures, delivered before Easter, Mr. Hullah said that the bow, to which he should now have to direct their attention, ought to prove an interesting as well as an important subject, for no mere mechanical appliance had ever made so many and such important changes in an art as the bow had made in music. Strangely disproportionate sometimes, however, is what is said about a thing to the thing itself. The poets of modern Europe seem never to weary in singing the praises of the lyre, the lute, the psaltery, and the harp—instruments, three of which no one living has heard, while the remaining one was only exceptionally brought in to the orchestra. Yet which of them has adorned the violin with an epithet worthy of its power, sweetness, infinitely variable

intonation, flexibility, and, more than all, power of expression? The violin, to one who has thoroughly mastered it, has ceased to be an instrument, however sensitive and responsive to his touch; it has become rather a part of his own organism—another member—an additional arm. Like a living thing, too, the violin has its humours, its waywardnesses, its good and bad moments. It resents ill-usage. Handled for some hours by an incompetent player, stopped out of tune and bowed badly, it will take time to recover its capability for correct intonation. The imaginative inhabitants of the south of Europe attribute to it a soul. Our sound-post is called in Italy *l'anima*, and in France *l'ame*. The characteristics of the violin family are the finger-board and the bow. As Mr. Hullah had said before, the former was a very ancient invention, certainly known to the Egyptians. Its existence is in no way dependent on that of the bow; and the bow existed long without association with the finger-board. This association, however, when brought about, enormously increased the value of both contrivances. The history of the bow—the time and place of its first application to a string—has afforded matter for much controversy. In investigating the origin of anything—invention, custom, or word—our thoughts involuntarily turn at first to the East; but in the instance of the bow we get little satisfaction, hardly even material for speculation, from that quarter. Instruments of the violin kind have been found in the East, but chiefly in those parts which have been directly subject to European influence; so that it seems quite as likely that the Hindoo or the Polynesian have taken these instruments from us as we from them. No one is bound to prove that the bow was not an Eastern invention. The onus rests with those who think it was, and their only means of raising it seems to be conjecture. The authentic history of the violin is altogether European. The earliest representation known of an approximate one (a copy of which was exhibited) is in the *De Cerva et Musica Sacra* of Gerbert. Gerbert assigned it to the end of the eighth century. The instrument represented has but one string, but in other essentials it is a violin, with a tail-piece, a bridge, two sound-holes, and something like a finger-board. The bow rests on the string, and the portion of the (right) hand shows that it was held like the violin of to-day. There is proof, however, that, anterior to the eighteenth century, a bowed instrument, having three or more strings, was well-known in the north, and not unknown in the south of Europe. It was called in England a crowd, and in Wales (beyond which it cannot be traced) a crwth. Two drawings of this instrument, of different dates, were then exhibited. They varied in the number of strings, and in some other respects, but were indisputably representations of the same kind of instrument. The bridge of one was nearly, and of the other quite, flat, which of course prevented the bow touching one string without touching two or perhaps all of the others, indicating that the earliest bowed instruments were used for the production not of melody, but of harmony, however rude that might have been. If this was so, it established the fact that the use of the bow and the treatment of combined sounds grew up together, and that the cradle of both was the north of Europe. The earliest mention of the crwth yet found is in an elegy addressed to Loup, Duc de Champagne, about the year 570, by Venatius Fortunatus, who, in the same passage had first used the word harp. The passage might be rendered thus:—"Let the Roman applaud thee with the lyre, the barbarian with the harp, the Greek with an heroic strain, let the British crwth sing." There the instrument is spoken of (by an Italian) as British, and (as Mr. Chappell has actually remarked) distinguished from the three others as capable of producing sustained sounds, like the voice. From the Celtic crwth come the mediæval words *rote* and *rotte*, which are not derived from the Latin *rote*, to turn, a

* N.B.—This is found to be very efficacious.

† The object of this is to give the communes an interest in putting the law in force. Other articles have been repealed which inflicted small penalties.

common error, fortified by the application of the word *ote* to more than one instrument, among them the hurdy-gurdy. This last, however humble its status now, was evidently once held in high estimation. It was called, in the early middle ages, the organistrum, and was no doubt used for organizing, i.e., accompanying melody in staves, fifths, and fourths,—an effect once thought pleasing. The organistrum is common in mediæval sculpture. A cast from a singularly fine example has just been placed in the Kensington Museum. It is held by two of the elders of the Apocalypse, who occupy the place of honour over the doorway of the Church of St. Iago da Compostella, in Spain. In calling attention to the drawings of bowed instruments (about twenty in number) on the walls, Mr. Hullah said a glance at them would show that in the course of development into the violin of to-day, the crwth had undergone metamorphoses many and great. Having regard to the limited time before him, he thought he could not trace those better than by passing those drawings in review. Before doing so, however, he would say a few words about the various names, or modification of the same name, which these instruments had borne. Most of them were connected with, if not directly derived from the Anglo-Saxon word *fithle*. This word was not disused in England till the beginning of the 13th century, when the Norman aversion to the *th* effectually changed it to *fiele*, and eventually *vièle*, which by easy transitions became *viol* and *viola*. The modern names *violino*, *violone*, and *violoncello*, are simply Italian diminutives or augmentatives, or both combined, of *viola*. These derivations or connections, however, have not been unquestioned. The Provençal form is *viula*, and the mediæval Latin, *vitula*, easily affiliated to *vitulari*, to leap like a calf—an expression which might figuratively, very figuratively, be applied to the motion of a bow. Mr. Hullah then called attention to (1) a *vièle*, from a corbel in the church of St. George de Boscherville, in Normandy, of the 12th century. It resembled the modern violin in having four strings, and being held under the chin; the form, however, was different, and the bridge flat. It was, therefore, an instrument of harmony, a fact confirmed by the player being represented singing. (2). A *vièle*, from a painted window in St. Denis, near Paris, of six strings. (3). A *vièle* in the hands of a monkey, over whose head was written *Neptunus*; from a MS. of the 13th century, at Douay. This was a great improvement on its predecessors, having expanded into a well-formed oval, with a disengaged neck—an important point. (4). Another *vièle*, of like form, from the façade of Amiens Cathedral. It had three strings only, and was resting on the knee of the performer. (5). A *oroth* (called in France a *rote*), also from Amiens, having six strings, and presenting a very early example of sound-holes like the letter S. (6). Another *vièle*, also from Amiens, so placed that its back could be well seen. It was flat, like the so-called Latin guitar. (7). An example of an instrument, the sides of which were *echancrées*, or curved inwards, from a window at Tiges. Mr. Chappell, whose opinions on such points were always worthy of attention, considers that the bent sides were invented “for the purpose of holding the instrument between the knees.” Mr. Hullah, demurred to this opinion *in toto*. Examples in ancient sculpture could, no doubt, be found of *echancré* instruments so held, and so could as many or more, in which they rested on the knee of the performer. The “bent sides” originated, he thought, in a very different cause. Though long used as an instrument of harmony, the capabilities of the musical string for melody and expression must have been early ascertained. The strings of the pear-shaped and oval *viols* he had exhibited were not individually accessible. The bow could not touch one without touching the others. But, by narrowing the sides of the instrument, the outer strings at least could be brought singly within reach of the bow; and so, by elevating the bridge, could the other strings. This great improve-

ment was not universally adopted for a long time. (8) A *vièle*, from a MS. at Brussels, of the 14th century, in its general aspect had more of the violin character than any of those previously described,—four strings, a bridge, a well-defined neck, and a bow of good length and pattern. (9, 10, and 11) Examples of the *geige* and *gigue* of Germany and France: differing little from the *vièle* in shape, but considerably smaller. The *gigue* was in great favour with the *trouvères*, who seldom mention the harp, *vièle*, and *rote* (their favourite instruments) without it. Though given up in France and the south, it maintained its favour in Germany till the 16th century, when the German name, *geige* was transferred to the violin proper. (12) A *rebec* (from a picture at Douay), called in the 13th 14th and 15th centuries the *rubee* or *rubelle*. It had generally two, never more than three strings, tuned, like the violin, a fifth apart. (13) A *vièle* of five strings, slightly *echancré*, and a fretted finger-board. The gentle curve of the bridge pointed to this as an instrument of harmony—the chords being necessarily executed in *arpeggios*. (14) An example of a *vièle* closely approaching the violin, with bold *echancrures*, and four strings, tuned by pegs. The steps from an instrument like this last to the violin, though, of necessity, many, could not have been difficult. Nor were there wanting artists to make them. Of some of these Mr. Hullah said he hoped to speak in his concluding lecture. What remained of the time before him he would rather devote to another musical apparatus, hardly less important than that they had been considering—the key-board. The key-board is obviously one of those contrivances the conception and perfection of which, in all that is essential, must have been simultaneous. It has a basis in nature; its proportions depending entirely on those of the hand,—the average length and strength of the fingers. The key-board for fingers, however, was preceded by one for the whole hand, the keys of which were a yard long and three inches wide. Key-boards, of like importance, are still in use for the *carillons*, so numerous in Belgium. They were applied generally to organs from the 11th to the 14th century, after which they gave place to the key-board, such as we now have it. The latter had probably been invented somewhat earlier, and applied in the first instance to instruments of the class which attained perfection in the harpsichord. Mr. Hullah then sketched rapidly the early history of the organ, adducing several proofs of its being of greater antiquity than is commonly supposed. He exhibited two drawings of organs from a bas-relief on an obelisk, erected at Constantinople in the time of Theodosius the Great, the fourth century. Even in Western Europe they were known in the fifth century, and at a somewhat later epoch many were to be found in our own country; at Winchester, for instance, in the 10th century, and at Canterbury in the 12th. Of the infancy of instruments, of the harpsichord class, Mr. Hullah said little was known. That they were widely spread in the 14th century is certain; that they were invented considerably earlier is very probable. Instruments of this class are long anterior to the pianoforte. The key-board acted long on the plectrum before it was brought to bear on the hammer, though the use of the hammer, like that of the plectrum, is of immense antiquity. Many names have been successively applied to these instruments. There was the *clavicytherium*, the *clavichord*, the *clavicembalo*, the *virginal*, the *spinet*, and the *harpsichord*—all, with whatever varieties, essentially the same instrument. The last and most perfect of them, the *harpsichord*, had now given place to the *pianoforte*. Probably, Mr. Hullah said, few present had ever seen or heard a *harpsichord*. He hoped next week, when he should meet his audience for the last time, to introduce to them, not a mere effigy, but a very tuneful specimen of this class of instrument, the “silence strings” of which he would find some means of “waking into voice.”

TWENTIETH ORDINARY MEETING.

Wednesday, May 1st, 1867; THOMAS TWINING, Esq., Vice-President of the Society, in the Chair.

The following candidate was proposed for election as a member of the Society:—

Whichelo, George, 14, Burnley-road, Stockwell, S.

The following candidates were balloted for, and duly elected members of the Society:—

Bailey, John, 163, Oldfield-road, Salford, Manchester.
Blacklock, Wm., J.P., Hopefield, Pendleton, Manchester.
Burton, Oliver, Tyldesley, near Manchester.
Henson, Henry H., Rutland-lodge, Watford, and 13, Parliament-street, S.W.
Sandbach, Wm. Robertson, 10, Prince's-gate, Hyde-pk.

AND AS HONORARY CORRESPONDING MEMBER,
Nobile, Signor Commendatore Gaetano, 14, Via Salata, ai Ventaglieri, Naples.

Previously to the reading of the paper, the Secretary drew attention to a form of self-acting buffer-break, invented by Mr. C. E. Parker-Rhodes, and intended for use on railways. The principal peculiarity appears to be that the buffer acts upon the break so as to produce a downward pressure on the wheels. The inventor states that his arrangement produces a gradual stoppage of the train, from the engine to the last carriage.

The Paper read was—

ON A MACHINE FOR TYPE-WRITING.

By JOHN PRATT, Esq., of ALABAMA, U.S.

Custom has so intimately associated the idea of writing with the implement employed in that very ancient art, that most persons, on reading the announcement of to-night's paper, will naturally be in some doubt as to what may be meant by "a machine for writing with type." On the other hand, printing having been for so many ages the sole purpose to which type has been applied, it is not, at first thought, readily conceived that type may be used for any other process. It is only necessary to recur to the true definition of the words writing and printing to reconcile the apparent contradiction. Printing is not, it must be borne in mind, the formation of letters of a particular shape, but of rapidly multiplying copies by means of a press and a bed of movable type—entire words, paragraphs, or pages being impressed at once. Writing, on the other hand, may be largely defined as the art of producing, no matter by what means, the first or original draft of a composition. Viewed in this manner, there seems to be nothing obscure in the title I have chosen for my invention; yet nearly every one to whom I have had occasion to mention it has seemed at first puzzled by the seeming contradiction of the terms "type," and "writing." But the idea of writing with type, though so incongruous, because so new to most persons, is not a sudden growth though a somewhat recent one. Indeed inventions, though children of the brain, are by no means Minerva-like in their birth. They are not manufactured. When questioned closely as to their origin and laid bare of the exaggerated claims of their authors and the enthusiastic statements of biographers, they will almost always return the unsophisticated but profound answer of Topsy to her New England catechist, "I specs I growed." Let me not be misunderstood. I am speaking of inventions, not of the thousand patent mouse traps, nutmeg graters, clothes washers and wringers which cumber patent offices in every part of the world, and perhaps tend more

than anything else to worry statesmen and journalists who should know better, into a peevish hostility to patent laws. No matter to what class belong the various essays to invent a substitute for the pen, their origin is not so remote as to be doubtful or obscure, as I shall be excused by their very recentness and consequent novelty for briefly noticing them before entering upon a description of my own effort. Before doing so I must premise that you must not expect me to describe a machine intended for, or proposed to be adopted in general use, as a substitute for the pen. There is none such. As well might you expect to find a living ancestor of the sewing machine. This species of development no more proceeds in a right line than the Darwinian, and allow me to say that in tracing its history you will often be encountered by a "missing link." Certainly the first modern printing-press is almost as far removed from the Chinese printing blocks, and Hargreave's jenny from the old-fashioned spinning wheel, as a free and equal "contraband" from his reputed ancestor in the Zoological Gardens. It would be presumptuous in me to claim as great a gap between my poor idea and analogous inventions already made. I do but say that I am the first to invest writing machine *par excellence*.

The first machine of this kind that I have seen mentioned, is a machine for the blind, invented by M. Foucault, and which was awarded a gold medal in the Paris Exhibition of 1855. The type in this machine was formed on the ends of a number of converging rods sliding in grooves cut on the surface of a metal plate. These rods were simply pushed to the point of convergence by the finger, where they produced a legible character by means of carbonised paper, the latter being moved as the writing progressed, by a pawl and rack. In Hughes' machine for the blind, which many persons have doubtless seen in the Kensington Museum, though not so rapid as Foucault's, is a considerable step in advance on the main idea, inasmuch as the types have a movement in common, and, therefore, cannot clank and clog as with separate converging types, competing as it were, to reach the same exact point. In the Hughes machine the types pass through the periphery of a circular plate, in a direction parallel to its axis. The plate revolves horizontally on its centre, and the types are successively wheeled to the point where the impression is made, which is done by pressing a lever upon the butt of each type. The whole mechanism is quite primitive, and works slowly, the plate being revolved by the hand, without the intervention of any kind of mechanism.

The next inventions in this general direction are the machines for "writing and making stereotype moulds," both by Americans, and patented in England, the one in March, the other in May of 1866. One of these, invented by Mr. John E. Sweet, is now in the Paris Exposition where, I believe, it has attracted considerable attention. Though differing much in detail, these machines agree in their salient feature, to wit, the mode of bringing the type to the point of impression. The types are ranged around the periphery of a wheel moved, like the type wheel of the printing telegraph, by clock-work, or by a crank turned by an assistant. In Mr. Sweet's machine the wheel revolves horizontally, and the types are ranged parallel to the axis; in the other invention, they converge towards the centre, like the spokes of a carriage wheel. In both machines, piano keys are employed, each of which stops a particular type at the point of impression; and both in this respect resemble the printing telegraph. The particular manner in which the key of one of these machines (Mr. Sweet's) perform this office, is very different from that employed in the printing telegraph, and displays much ingenuity.

Several other inventions have been made or attempted for printing and writing, which I need not more than mention. In 1864, a Frenchman, M. Bryois, filed a provisional specification in the British Patent Office for

stenographic machine. It was a crude idea, based on the principle of converging levers. In August, 1866, an invention for "writing and printing" was patented in the United States by a Mr. Peeler, somewhat resembling, I believe, the Hughes' machine for the blind, one lever only being employed for the impression and for controlling and moving the type, instead of a number of keys, and, therefore, like the Hughes' instrument and the one-keyed telegraph, necessarily slow. Finally, on the 21st of last March, a paper was read before the Polytechnic Institution in New York, descriptive of a machine, also for "writing and printing," by a Mr. Hall, which employed piano-keys, and a type-wheel, acting, like the other wheel instruments, on the same general principle as the printing telegraph. I have not described particularly the manner in which, in these various inventions, the paper is moved over the point where the impression is made; nor is it necessary to do so, as the operation itself, of feeding material as it is worked up, is common to many other inventions, and they all adopt a device analogous to that of the sewing machine.

It will be seen, from what I have said, that considerable progress has been made towards the invention of a writing machine. In the first place, the idea has germinated in many different minds, in widely separated parts of the world, that type may be substituted for the pen, in producing the original draft of a composition, as well as in multiplying copies. Again, we find the idea developed that only one set of types must be employed, that they must be brought to the same point in arbitrary succession, a corresponding impression formed there, and, at the same time, the paper which receives the impression move automatically as the work requires. And, in every case, we find carbonized paper employed instead of fluid ink. Nor are these ideas merely theoretical. Most of the machines I have mentioned do very good work, and are a great improvement upon the pen in legibility at least. They all have one defect, which must prevent their employment as substitutes for the pen. They are too slow,—those employing converging type, because of the interference of the types with each other; those employing a type wheel, because of the distance to be traversed by the type. The machines employing piano keys, and constructed on the principle of the printing telegraph, are also objectionable, on account of their great costliness, their cumbrousness, and the necessity of employing extraneous power, or otherwise clockwork, which requires winding up at very frequent intervals. In the case of the telegraph, and of machines for making stereotype moulds, a high speed, though desirable, is not necessary, and the expensiveness of the machine is comparatively unimportant. With a machine designed as a household or ordinary office implement the case is otherwise. Again, machines like those invented for the use of the blind, though sufficiently economical of construction, are even less rapid and less adapted for general use.

I must now approach my own invention, which I do, I assure you, with great diffidence; I know that I have undertaken to do that which many will say is impossible—and say it, perhaps, after I have exhibited the operation of my instrument—to wit, the useful substitution of machinery for manipulation, in an art requiring only less arbitrary and varied movement than that of which its hieroglyphic origin proves it to be the offspring—I mean the art of drawing. Besides this, I am conscious of having as yet fallen far short of the goal at which I aimed at starting, namely, the invention of a machine possessing sufficient rapidity for *verbatim* reporting. Observe, I say I have fallen far short, not failed, for I am confident that a machine may be, and will be, constructed on my principle, sufficiently rapid to record, with the aid of a phonetic alphabet, devoid of word signs, every sound as fast as it is uttered in ordinary conversation. I have not, however, practically developed the idea to that extent; indeed, I have fallen far short of it. The instruments on

the table are capable of a rapidity only about twice that of the pen when used in long hand.

Though not so rapid as might be desired, the art of writing with the machine is so simple, that a child will write with it, at its first essay, almost as well as ever after. To acquire rapidity is a work of greater time and labour, although insignificant when compared with that requisite for the mastery of a swift hand with the pen. I have myself been too much occupied with perfecting the invention, and have changed too often the arrangement of the keys, to pronounce definitely how long a time must be occupied in bringing out the full capacity of the machine. I can only say that, after about two weeks' practice, at the rate of two or three hours a day, I can write, with the arrangement of keys I now employ, about as fast as with the pen—say twelve folios an hour. I will explain hereafter my device to still further increase the rapidity of the instrument. For the present, I must be satisfied to claim a rapidity, capable, I think, of demonstration, twice that of the pen, with the legibility of print. Now for my apparatus.

Keeping in view the manner in which the types are arranged and moved to the same point in the inventions I have outlined, and the cause of their low speed, namely, the interference of the types when converging, and the great distance through which they must move when brought to the point of impression by the revolution of a wheel, the problem to be solved by a successful invention of the kind assumes a definite shape. It is so to dispose the types that they may have the smallest possible distance to traverse, in order to arrive at the point of impression. For this purpose it is obvious that it is most advantageous to arrange them in a number of series in the form of a square, instead of in a single line, as in the wheel machines. Thus disposed, the distance to be traversed by the most distant type, is only the square root of what is necessary in the other case. Thus, taking the dimensions of a single type as the unit of measure, if 36 characters extend $\frac{1}{4}$ of an inch when ranged in one series, they will extend only one-sixth of that distance, or three-eighths of an inch, when placed in the form of a square. But in order that the type may be successively brought to the same point, the plate must have a great variety of movement, both as to direction and distance, and this variety must be differentiated, so to speak, out of one simple vertical movement of a number of levers. The solution of this geometrical problem is the main feature of my invention, though I may as well observe, here, that my methods of moving the paper, and making the impression are also new.

The whole mechanism is contained in a small case, composed of two rectangular frames, mounted the one on the other, giving the side elevation an L shape. A number of levers, furnished at one end with keys, extend from front to back the interior length of the case. Extending across, and a short distance above these key levers, near the back of the case, are two oscillating plates or rocking frames. Between the fulcrum of the key levers and the oscillating plates just mentioned is a third oscillating plate, also placed above and across the key levers. These three oscillating plates are moved simultaneously by each key, and perform simultaneously the three different operations already mentioned as requisite in a machine for writing with type, namely, bringing the types in arbitrary succession to one point, forming a corresponding impression there, and moving the paper.

First, the manner in which the types are brought to the same point. These are disposed in slight converging lines on the face of a thin metal plate, which, for economy, is electrotyped in the ordinary manner. This plate is worked by the simultaneous and combined action of the two oscillating plates at the back of the case. If you will bear in mind the connexion between a line and a single force on the one hand, and area and compound force on the other, you will more readily conceive the *rationale* of this part of the

mechanism. With one of these oscillating plates, the type plate is connected by a vertical lever, to the upper end of which it is fixed, being supported at its back by a metal bar. With the other oscillating plate, it is connected by a bell crank lever and two wire links, one of which extends vertically from the horizontal arm of the bell crank to the oscillating plate; the other passes horizontally from the vertical arm of the bell crank to the lever to which the type plate is attached. If only one of the oscillating plates be moved, the type plate moves in only a vertical or horizontal direction, according to the one employed. When both are moved together, the resultant motion of the plate is diagonal. By varying the relative degree of the two movements, the direction of the type plate is equally varied, and any given type may be moved to any desired point. In other words, by varying the relative amount of movement of the oscillating plates, the vertical or horizontal movement of the type plate may be made to preponderate, more or less, in an indefinite degree. This variation is effected by adjusting screws, which pass vertically through the key levers, and impinge against the under surface of the oscillating plates. Through these screws, the key levers, though having the same relative movement, communicate each a different degree of movement to the plates, and this difference in extent becomes a difference in direction when the motion is transmitted to the type plate. A machine, when finished, is adjusted in a manner very analogous to the tuning of a pianoforte, with the important difference that performers may tune their own instruments in a few minutes, and may also consult their own taste in the arrangement of keys. The motion of the type plate is checked at the proper moment, to receive the stroke of the type hammer, by springs, which oppose a moderate and nearly uniform resistance to the movement of the oscillating plates.

The Society will perceive that I have presented two models for their consideration. These instruments, although employing a different number of keys for the same number of types, are identical in principle. In one, the oscillating plates extend across the whole number of key levers, so that every lever may operate both plates, and thereby exert a complete control over its respective type; in the other, they extend only half the lateral space of the levers, each lever operating only one of the plates, and therefore producing only one movement of the type-plate, so that it becomes necessary to depress two keys at once in order to bring any given type to the impression point. The variety of movement requisite to control the whole number of characters is procured by employing the keys permutatingly, each key being employed in conjunction with a number of other keys. This arrangement, although open to the objection of requiring the simultaneous employment of two keys—an objection which, at first, caused me to reject the idea altogether—has the advantage of requiring a much smaller number of keys, for, since each key controls a row of types instead of a single type, the number of keys need only equal the number of horizontal and vertical rows; in other words, twice the square root of the number of types. For instance, if there be 64 types arranged in eight horizontal and eight vertical rows, the number of keys need be only 16.

For convenience, I have arranged the keys which give the plate a vertical movement on the right-hand side, and those which move it horizontally on the left-hand side of the machine, leaving some space between them. This, however, has nothing to do with the principle of the invention, as the other instrument also may, without removing or adding a lever, be so adjusted as to require the simultaneous depression of two keys, in which case all the keys beyond twice the square root of the number of characters become supernumerary. There was, however, a considerable practical difficulty to be overcome in adapting this arrangement. This was the deflection of the plate from a right line in its vertical movement, caused by the arc described by the horizontal link con-

necting the bell crank lever with the type plate lever. Thus, if I keep depressed the key which brings the first left-hand series of types under the hammer point, and meanwhile depress a key which moves the plate downward, the arc described by the link will cause the character at the upper end of the series to be deflected to the left about one hundredth part of an inch, an error of great consequence in so nice an operation as writing at all accurately with type. This might have been remedied by having the characters engraved on the plate in lines, having a counter curve of a radius equal to the link, had it not been for the necessity that they should converge towards the hinge of the type-plate lever. I finally overcame the difficulty by hinging the bell-crank lever to a second lever, to which I give a movement to the right, by means of a link attached to a lever operated by one of the oscillating plates. These are described by the last-named lever neutralizes the arc of the bell-crank link. Engineers will doubtless perceive the analogy of this device to the parallel motion of Watt. In this parallel motion the problem is complicated by the circumstance that the link whose arc is to be compensated is hinged to a shifting centre, namely, the upper arm of the bell-crank lever.

I hope I have said enough to convey a sufficiently accurate idea of the manner in which the first operation of my machine is performed. I have been somewhat tedious in the description of this part of my invention, because I am not aware of any analogous employment of compound motion, in any branch of mechanics, to produce indefinite variety of direction.

In describing the second operation of my machine—namely, the impression—I shall be very brief. It is effected by a hammer, having a face equal in extent to a single type, which strikes against the several types the instant they are brought within its range, a sheet of carbonized paper held in contact with a sheet of writing paper. Transparent transfer paper may be also employed, as well to enable the operator to see the progress of the writing, as to preserve a copy. The hammer is operated by an oscillating plate, with which it is connected by a small rod hinged to its butt. This rod has at its lower end a catch, which engages an arm projecting from the oscillating plate, and having an eccentric movement, which causes it to act in a manner somewhat analogous to the hopper of a piano. The depression of a key lowers this eccentric arm, and retracts the rod and hammer. Just as the key has been carried through its full movement, and the corresponding type brought to the proper position, the catch is pushed off the eccentric, and the hammer impelled against the type by a spring. The exact moment when the hammer is released from the catch—a matter of great nicety—is determined by a screw adjustment. When the key is released, the arm of the oscillating plate again engages the catch, and the hammer is ready for a new stroke. It is therefore necessary, with this arrangement, to release one key before striking the next; and it is this necessity that limits the rapidity of the instrument, which otherwise might strike off printed characters as fast as the piano can yield consecutive notes.

I have overcome this difficulty by applying the device for operating the hammer to each one of the key levers, instead of to the oscillating plate, and thus there are always a number of levers ready for action. The principle and efficiency of this device, which has not yet been applied to the machine, I have demonstrated by a partial model employing only the mechanism requisite for operating the hammer. This modification, however, is not adopted as a mode of removing a defect, but of adding to rapidity, which will be found already sufficient for the requirements of most operators.

Now for the feed of the paper. A square open frame, which for distinction may be termed the page frame, slides in vertical grooves formed in the upright part of the case, in the plane of the type plate. Within this, a second frame, which may be termed the line frame,

moves horizontally from right to left. The movement of the latter makes the lines, and of the former the pages, of writing. The movement of the line frame is given by a square steel rod revolving in vertical bearings, and moved by a spring, which is wound up at the completion of each line by striking a key. The motion of the rod is communicated to the frame by a small pulley, turning with the rod upon which it slides with the page frame during the progress of the writing. Its movement is regulated by an escapement wheel and pallets, the latter being connected by a link with an arm projecting vertically from the oscillating plate which operates the hammer. The same key-stroke which moves the hammer produces an oscillation of the pallets, and allows the paper to move the distance of a letter and space. The oscillation of the pallets may be effected by a partial movement of the keys, so that the paper can be moved without moving the hammer, when it is required to make a space instead of a letter. By this means I get rid of the space key used by all previous machines of this or an analogous class, every key serving as a space key. The carbonized and writing paper are held in a clamp resting loosely in an angular projection of the line frame, whence they are easily and quickly removed for a fresh sheet of paper.

It only remains to show how the paper is brought back to its starting point for a new line. To reverse the movement the escapement wheel must first be freed from the pallets, which for this purpose are mounted on a lever, connected by a link with one of the key levers, and the depression of which effects the disengagement. This done, a second key must be struck, which operates a link, bell-crank lever, and toothed sector, thus reversing the movement of the frame and bringing it to its starting point.

To make the proper interval between the lines, the page frame is provided with a rack, moved by a pawl of peculiar form and adjustment, which leaves the teeth always free, so that the frame may, at any stage of the writing, be moved in any direction. The pawl is operated by aid of one of the key levers with which it is connected by a vertical link rod. A page being completed, a new sheet of paper is placed in the clamp, and the page-frame is pushed back to the bottom of the grooves.

To judge from the length of time it has taken to give a rather general idea of my invention, one might be led to suspect that it is a very complex affair. But I think it will generally be found in machinery that the most complex idea, if fully matured and thoroughly developed, is the simplest and most economical to embody in the actual machine. At least, I know this to be the history of my own invention. My first effort was based on the simple and comparatively obvious idea of converging rods; and yet, if you could compare a model which is still, I presume, in the lumber-room of a pianoforte manufactory in Glasgow, with those on the table, you would perceive a great improvement as regards simplicity and economy of construction. I may as well mention that these possess another important quality lacking in my first machine, namely, the capacity of writing—a feat the other, though otherwise unexceptionable, wholly refused to perform.

But I think a glance at the construction of these instruments is sufficient to convince those who have a knowledge of machinery of their simplicity and economy. The case is small, compact, and being subject to no strain, must last indefinitely. The key levers, which are of wood, are strung on a polished steel wire, and work on the cloth centres, so serviceable in the piano, and so cheaply renewed when worn. The oscillating plates and hammers are also of wood, working in similar bearings. The other levers are lined on vellum joints which cost little and last almost a lifetime, and, finally, the links immediately controlling the type plate work in india rubber joints which have no friction, no wear whatever, and can never become loose. The only parts of the machine which must be

of metal are the type plate, the hammer head, the escapement wheel and rod, and a few pieces of steel and brass wire. The type, not being subject to any corrosive action, and being protected by the leather which covers the face of the hammer, will last almost indefinitely, and when worn out—of which I, in my brief experience of the matter, have seen no indications—may be replaced for a penny. Again, owing to that peculiar feature of the machine,—the screw adjustment of the type—type plates of different sizes, styles, and having various complements of type, may be employed in the same machine. To recur to the question of simplicity and economy of construction, which in an invention of this kind is of special importance in estimating its utility, I will merely add that, with sufficient capital to manufacture on a large scale, it may be easily sold at a very large profit for three guineas, a sum not much greater than the cost of the paper that would be saved by a year's employment of the machine in an office having much correspondence, and but little more than the copying press now used in all counting houses, and which would be rendered useless by the adoption of this writing machine.

A larger and more interesting question than the question of economy of manufacture is behind. Is there a want, and does the invention supply it? If the pen is everything that is required in the combined qualities of legibility, accuracy, rapidity, and ease of mastery, then this invention is useless. Again, if this writing machine is not more rapid, legible, accurate, or easier to learn than the pen, it has not supplied the want, and some inventor possessed of greater ingenuity, more patience, and fortitude under discouragement, or more abundant means and leisure than I, must and will come to the rescue; for civilized man knows no real want which civilized man cannot supply.

It is almost needless to show the existence of a want of a brain-tool better than the pen. Its inaccuracy quashes indictments, increases and breeds litigation, and hinders and delays the law-suits it engenders. Its obscurity and illegibility obstruct the author in criticising his composition, the publisher in estimating its worth, and the printer whose eyes are worn out in trying to decipher it. In short, it increases the cost of books, and diminishes their literary value. In private and public correspondence this defect of the pen is felt as almost a nuisance. I say felt, because as long as it is not clearly seen that an implement may be improved, or wholly or partially supplanted, its shortcomings are very naturally attributed to want of skill in the operator.

The next question is, what a machine of this class must be capable of accomplishing in order to be useful, other things being equal. This is a question that will receive various answers from different individuals, but perhaps there are not many who will pronounce useless a cheap and durable machine, having even the rapidity of the pen, the legibility of print, so easily understood, that a child that cannot write with the pen will write as well with the machine as after a lifetime of practice, and so easy to master that, after a few weeks' leisurely practice, one may write as fast as with the pen. At this point, then, I shall stop. It may, it is true, be demonstrated that the machine possesses a far higher capacity for speed, for by striking the keys at random more than twice as many letters may be formed in regular succession as with the pen, and by adopting the modification of hammer stroke referred to in the description of the machine, there is no limit to rapidity, except what the nerves and muscles of the operator impose. But I repeat, that I shall be content to bring the invention up to the criterion first named, and which my own very brief use of the machine demonstrates can be done.

After reading the paper, Mr. Pratt explained in detail the various parts of his machine, and exemplified its practical working by copying a paragraph from a newspaper that had been handed to him.

DISCUSSION.

Mr. CAMPIN said he was afraid he did not quite understand the details of this invention, which, however, appeared to be a very ingenious one, and likely to have its uses. There were one or two points, independent of the nature of the machinery, which he would be glad to be enlightened upon. In the first place, he would ask whether this machine would produce a number of copies of that which was written or only one?

Mr. PRATT replied it would give three or four copies at once if required.

Mr. CAMPIN further inquired whether there were the means of correcting inaccuracies as was done in ordinary writing, by striking the pen through the word and re-writing it, or by interlineation. One point which struck him was that, if this invention were brought into use, they would not have the advantage which they now had of identifying a person's letter by his handwriting, because all letters would be in the same printed type.

Mr. GALLOWAY asked whether this was proposed as a new system of printing generally?

Mr. PRATT, in reply to Mr. Cowper, stated that corrections and interlineations could be made as readily by the machine as with a pen. If a wrong letter or word was written, it could be erased, and another put in its place. The paper could be run back to the same point, and the interlineation could be readily made; there was no difficulty whatever about that. In answer to the last speaker, he would state that this invention had nothing at all to do with printing. It was simply a writing machine, which would work more rapidly than the pen, and the result would be more legible. As a matter of course, this machine did not furnish the means of authenticating documents. The machine was not intended entirely to supplant the use of the pen, any more than the sewing machine would ever supplant the use of the needle. There were some things which the sewing machine could not do, and it was the same with this machine. It could certainly not be employed in book-keeping and the making up of ledgers. It was a machine the use of which was so readily acquired that it might be superadded to the accomplishment of writing with the pen. It was brought forward as a good substitute for the pen for writing letters or manuscripts for the press, and he thought for law-stationers it would be valuable, because it was so much more legible and so much more easily acquired than writing, and one person could write with it as well as another, when the operation was confined to the mere copying of documents.

Mr. CUBLEY, in reference to the question of the multiplication of copies, said it was often the case that from ten to twenty copies of law papers were required, and it was necessary for the type to be composed for that purpose. He wished to ask whether it would not be practicable, in this machine, to have several frames arranged so that one set of keys could move the whole, and as many copies as were required struck off at one operation?

Mr. PRATT replied that the machine, as at present constructed, could furnish three or four copies of a document, in which case very thin paper must be used. In cases in which twenty or thirty copies were required, he thought they could be produced more economically by transferring an impression to the lithographic stone. A paper written by the machine with the thick oily ink he used, could be transferred direct to the stone, and any number of copies could be printed from it.

Mr. CAMPIN inquired whether ordinary writing paper could be used, or whether it was necessary to use the paper employed for manifold writing?

Mr. PRATT replied that three or four copies could be produced on ordinary note paper, provided it was not of extra thickness. Specially prepared paper was not required. In reference to the specimen of writing which had been handed to the meeting, Mr. Pratt said any

mistakes that occurred were his own fault and not that of the machine.

Mr. GALLOWAY thought that the time required for the operation was as great as, or greater by this process than by the ordinary method of writing. With respect to its application to letter writing, they knew that in mercantile transactions the handwriting formed an essential element, therefore he felt the invention would have much to contend with on that ground.

The CHAIRMAN said it now devolved upon him to ask those present to pass a vote of thanks to Mr. Pratt for his able paper, describing a most interesting, and, as he hoped it would prove, a most valuable and useful invention. He had no doubt the meeting would cordially join in that vote.

Mr. W. H. BONNEWELL said he hoped it would go forth that in passing that vote of thanks to the author of the paper, the meeting endorsed the feasibility of the invention which had been brought before them this evening. He would be sorry to throw any discouragement upon an ingenious invention; but having had some experience in these matters, he felt himself compelled to give an adverse verdict upon it. He recollected two or three years ago, there was an ingenious plan brought before this Society for boat-building by machinery, and a company was formed for carrying it out, but the whole thing was a signal failure, though it went forth to the world with a kind of impress from this Society as to its merits, in consequence of a vote of thanks having been passed to the reader of the paper. He would therefore say, while he quite concurred in a vote of thanks being given for the great ingenuity displayed in the construction of the machine, at the same time if that vote was to be regarded as a verdict in favour of it, he should feel disposed to dissent.

The CHAIRMAN said he hoped it was quite understood that this Society did not pledge itself in any way to the merits of anything which was brought before it. A machine of an ingenious character had been ably described, and with regard to the passing of a vote of thanks to the gentleman who had done so he was sure there could be but one opinion.

The vote of thanks was then unanimously passed.

Mr. PRATT, in acknowledging the compliment paid him, said it would be an ungracious act on his part to attempt to obtain from this meeting any special recognition of the good qualities of the machine he had brought before their notice. His object in reading the paper was merely to describe the machine, but the brief explanation he had thus been able to give would not be sufficient to establish its merit or demerit. Experience alone could do this. He had merely brought it forward to let it be known that there was such a machine in existence, and he left it in the hands of the public for what it was worth. He begged to thank the meeting for their kind acknowledgment of his paper.

Fine Arts.

PARIS ANNUAL EXHIBITION OF WORKS OF LIVING ARTISTS.

The Salon opened, according to announcement, on the 15th ult., and now competes, to a certain extent with the Universal Exhibition. The number of paintings collected in the Champs Elysées is 1,581, or more than four hundred less than last year. It is said that the admission jury was excessively severe, and undoubtedly the number of very bad pictures is not large this year; unfortunately, the absence of works of striking merit is equally beyond question. Few of the leading artists exhibit, and those who do have generally sent small works. The great room, or *salle d'honneur*, is relatively poorer than the rest, for the two chief places are occupied by pictures which are more remarkable for size than for merit. One of these is the "Tapis

Vert"—the gambling-table of Baden,—by Gustave Doré, which exhibits fertility of conception, daring colouring, humour, an eye for character, but sadly wants composition, harmony, and elevation in the treatment; the other is an immense decorative composition, by M. Puvion de Chavannes, called "Le Sommeil."

The most remarkable pictures in this principal room are—"The Abandonnée," by M. Schreyer, a young artist who obtained medals in 1864 and 1865. The subject is not highly attractive; a cart on a bleak moor, the carman and one horse dead, struck down, perhaps, by lightning, and another horse imprisoned in his harness, and apparently nearly dying of hunger; the last-named animal being painted with rare talent. "Feuilles d'Automne," by Hébert—an exquisitely painted forest lane, carpeted with yellow leaves, along which passes a melancholy female figure in black; the same artist has in another room a fine characteristic figure of a gipsy woman. "The Promenade," by Heilbuth; a cardinal is walking on a terrace, and gives his hand to a child to kiss, two footmen looking on with most comic gravity; the picture forms a companion to the meeting of two cardinals exhibited a short time since by the same artist. "Byblis changed into a stream," from Ovid's metamorphoses, is a good made study, by Henner, who has received all the medals. "Pius IX. in adoration before the statue of Saint Peter," with a priest and peasants prostrate on the pavement, by Jules Joseph Lefebvre, a young artist who won the prize of Rome in 1861. "An Episode of Saint Bartholomew," by Isabey, who has exhibited but little of late, a small picture of the interior of a church desecrated by frightful massacre, painted with admirable force and effect. Two charming flower pieces, by a young artist named Maisiat. "The Prince Imperial entertaining his young fellow soldiers in the Bois de Boulogne," a cabinet picture by Yvon, the well-known painter of battle-pieces. "His Highness on a Journey," by the clever artist Knaus, of Dusseldorf; a German officer, whose face is wrinkled with care, is followed through a village by two other officers, one fat and full of mischief, the other a young military dandy of the first water; the schoolmaster, the notabilities of the place, and a crowd of children, bowing, smirking, and staring in the most amusing manner, while a little dog, in no way awed, barks furiously at his excellency. The attitudes and faces are admirable, full of humour and variety, exquisitely comic, but all kept fairly within the legitimate bounds of art. M. Cabanel has only two portraits, one of the Procureur-General, the other of a lady, but they are certainly not equal to other works by the same hand. "The return from the Crimea," by Protais, a party of soldiers on the deck of a ship, many of them wounded, hail their native land with intense and varied expressions of interest; the picture is interesting, but the artist has produced better works. "Visit of Josephine de Beauharnais to her husband, confined in the Luxembourg," a pleasing picture by Viger. A large and well-painted picture of a slave market, by Victor Giraud, a young artist, holding forth good promise; the prosaic air of the richly-dressed purchaser, and the varied attitudes and expressions of the slaves, are expressed with great effect. An admirable view of one of the famous rooms in the museum in the Hôtel Clugny, by an older painter of the same name—Charles Giraud. A fine portrait of the Archbishop of Paris, by Lehmann; "Queen Hortense dispensing charity at the fine old Chateau of Ecouen," a pleasing composition, by Eugène Lejeune; a somewhat formal representation of the arrival of the remains of Napoleon, by a well-known artist, Felix Philippoteaux; "Job and his Consolers," by Lecomte Dumouy, a large composition of some merit; a pretty pastoral scene, three peasant girls returning from the fields, one of them with an arm thrown over the shoulders of her two companions, and a child with a poppy in its hand, by an able artist,—Jules Breton; a somewhat meretricious

picture of Napoleon when First Consul at the marriage of Janet, by Jules Masse, a pupil of Delacroix. One of Meissonnier's gems, a party at the door of a roadside house, the chief figure, a cavalier, admirably posed; the work has not so much interest as many others by the same artist, but the treatment and costume are out of his general style, and therefore present a new phase of his ability, and the handling is exquisitely delicate. Lastly, four landscapes, two by Rousseau,* in his usual style, scarcely supporting his deserved reputation; and two by our countryman, MacCallum, which attract great attention; one scene is laid in Windsor Forest, and challenges criticism from the strange, flat, yellow tone which pervades the whole picture; but the other is, unquestionably, a magnificent work; it represents a clump of oaks on a rising knoll in the forest of Sherwood; and the rendering of the trees, the perspective, and the atmospheric effect, are most remarkable; the picture is very large, and original in treatment, and is certainly one of the gems of the *salon*.

The following are a few notes made during a first visit in the other rooms of the exhibition:—A pretty "Psyché," by an artist of standing, Amsuray Duval; a charming young nude figure, entitled, "Idylle," by a rising artist, James Bertrand; a pretty quaint composition, "The House of the Painter at Pompeii," the artist engaged on a mural decoration, by Biennourry; a charming picture, called "Ribéra painting at the door of the Ara Coeli at Rome," a little child in bright-coloured apron, standing in the centre, against the old gray wall, and several other figures; and a curious, but powerfully-painted female figure, called "Gaby," by the same artist; a picture, called "Le Mamillare," representing the toilet of an antique dame, treated somewhat after the manner of Gérôme, by G. R. Boulanger; "The Sixth day of Creation," a most curious attempt to represent an unapproachable subject, by Brion; an exquisite study of a "Young Girl of Rhodes;" and a pretty little composition, "A Jewish School at Tangier," by Madame Henriette Browne. "La Lectrice," by Comte-Calix; a beautiful girl in mourning (a governess, probably), is reading to a family; two youngmen watch her with evident devotion, while the mother of the family regards her with attentive eye; the composition is rather stiff and mechanical, but the poor reader's nervous face is painted with great skill. The same artist has another picture, called "The Rural Postman;" the jolly factor seated at a well-covered table in the kitchen, while the ladies chat with him and the servants laugh in chorus; an excellent bit of comic painting. M. Comte, a well-known artist, contributes a picture of Henry III. during the assassination of the Duke of Guise; the cowardly king listens with his ear close to the door, his face pallid with terror, while two flaming candles throw a lurid glare over the whole; a powerful but very odd composition. M. Gérôme only exhibits two small pictures, "The Slave Market" and "The Dealer in Wearing Apparel, at Cairo," both most carefully-painted and attractive pictures, but not to be ranked with his best works. M. Eugène Giraud presents us with another daring glimpse of "The Opera Ball," treating a hacknied subject with considerable originality, but scarcely succeeding in telling any tale. M. Hamman pays an excellent tribute to Meyerbeer, who is represented as if in the act of composition, while the creations of his art flit like genii around the musician. M. Landelle has a small but admirably-painted work, "Jewish Tales of Morocco," transcribing the laws of Moses for the synagogues; two figures full of study and character. M. Müller has produced a good picture of Galileo in his captivity, visited by the nobles of Siena. M. William Wyld, a charming work, entitled "Souvenir of the Bay of Naples."

* Such are a few of the more salient points in the Paris Salon of the present year, which has so for-

* Whose name, like that of Meissonnier, does not appear in the catalogue.

midable a rival in that of the Champ de Mars; there is little doubt that the latter has robbed the former of many an ornament, but the salon presents an admirable collection of average French art at the present moment, and therefore deserves careful examination. There is certainly less originality, and at the same time less eccentricity, to be noted than usual, but there is a positive advance in drawing, manipulation, and colouring.

ART IN THE PARIS UNIVERSAL EXHIBITION.—The French sculpture may scarcely obtain the attention its high excellence deserves. It does not gain effect by concentration on any one point, but is scattered about as a means of decoration. Yet, collectively, there has seldom been a finer or more instructive display, even in an International Exhibition. These works are worthy of special study on several grounds. First, because no national school is better acquainted with the human figure than the French, or shows more mastery in drawing or modelling. And secondly, because this knowledge of the figure extends itself from the sphere of sculpture proper into the decorative arts generally. Thus, a chief reason why French bronzes are the best in the world is, that French sculpture in marble is decisive in form, sharp in the articulation of a joint, firm in the definition of a muscle. In short, our English artisans will do well to determine, on the evidence furnished by the French courts generally, how far those teachers are right who insist on the study of the figure as a preliminary and groundwork to decorative design. For this end it will be wise to pass from French sculpture to French manufactures, to mark how figures first modelled in the clay have been reproduced in bronze, zinc, iron, or the precious metals; to observe how knowledge of anatomy and a decisive and firm hand are turned to good account in the carving of wood and in the design and decoration of furniture. The best means, perhaps, of arriving at an intelligent understanding of the complex school of French sculpture is through a distinctive classification. It will be well, for example, to examine the 215 figures which constitute the collection under the following heads:—Schools antique, schools romantic, schools naturalistic, and sculpture portraiture. The collection is so far thorough that it will be possible, at the cost of some labour, to determine the strength or the deficiency of modern French sculpture in each of these departments. To enumerate names or mention individual works which are almost wholly unknown in this country would answer no good end. Perhaps it will be more to the purpose to point out what characteristics the student should look for, and what the excellencies or defects he is likely to find. In the revival of the antique it may be said that the French have properly seized on the old severity, and that their decision and firmness in modelling give them in this line a speciality. In their life-size bronzes, in which they naturally recur to Pompeian precedents, they also have a speciality. Some such figures are, perhaps, pushed needlessly into archaicism. Cavelier's "Neophyte" may be quoted as a very perfect example of the adaptation of the antique to modern art. Coming to schools of romance it will possibly be found that the French are surpassed both by the Italians and the English. Baily's "Eve at the Fountain," were it in Paris, would show a purity of sentiment foreign to a French work. Sentiment, it will be seen, the French push rather far; Moreau's "Studiosa" is, however, a figure of tenderness and beauty. It will be discovered that the French are strong in naturalism after its varied forms. "Chactas at the Tomb of Atala," by Gruyère, is a novel and striking example of naturalistic sculpture. Capellaro models a "Labourer," suggested by Virgil's "Georgics." Then, Cambes gives, in "La Cigale," an elaborate study of naturalistic drapery. And here it may be recommended that the various styles or treatments of drapery should be noted—the classic, the natu-

ralistic, and the generalized romantic. The exhibition contains fairly good examples of all. The German school of drapery has been known as singularly learned; the paucity of German sculpture is to be lamented. French naturalism is sometimes pushed into the picturesque or grotesque, as in the bronze statue of a "Negro," by Lequesne. Works wherein the whites of the eyes are actually represented by light coloured stone or enamel have been found at Pompeii. Such figures are, generally, not Greek, but late Roman; and the art is poor, not to say corrupt. In busts and portrait-statues the French show their accustomed aptitude. The sculpture, indeed, which is true in naturalism seldom fails in portraiture. Three works in this department specially deserve notice, both for excellence and as distinctive in treatment. Guillaume's "Napoleon I." is essentially statuesque and monumental; severe and stately. Carpeaux's "Prince Imperial," with a dog, deservedly one of the most popular figures in the exhibition, is picturesque; and Thomas's "Mdlle. Mars" is perfect as a statue of costume. Finally, it may be worthy of remark that the mediævalism of sculpture, that the styles which have risen responsive to Gothic revivals, find little place in Paris. The well-known statue of "St. Louis," by Montigny, given by the Emperor to the church of St. Louis d'Antin, partakes of a severity and dignity befitting architectonic sculpture. Also Dubois's striking figures show exceptionally the influence of the middle ages. "Narcissus" is allied to Michael Angelo, "The Infant St. John" to Raphael, and "The Florentine Singer of the 16th century" to Donatello.

Colonies.

RESOURCES OF NEW SOUTH WALES.—The Sydney catalogue of the articles sent to the Paris Exhibition is in itself an exposition of the resources of the country. The articles comprise wool, preserved meats, horns, hides, tallow, wheat, barley, oats, tobacco, cotton, wine, flax, silk, sugar, coal, iron, gold, and copper. Wool was the first of the industries of New South Wales, and is still the greatest. Ambitious as the colony is of getting out of the pastoral stage, and becoming a country of manufactures as well as a country of shepherds, the kind of pastoral development has not yet been reached. A considerable portion of the interior is still lying waste, and in a few years there will be millions more sheep than now. In the settled districts the land is being enclosed, and it is proved that fenced land carries more sheep than unfenced land. It is impossible to name the quantity of sheep the colony is capable of nourishing. In the quality of the wool produced there is much need for improvement. Those who have paid attention to breeding get more profit from the wool of one sheep than others do from two. Increased care is now being given to breeding for wool. Of late years attention has been paid rather to quantity than quality, and there has been, in consequence, some deterioration in the fineness of the fleece. But the tide is now turning, and an increased number of sheep farmers are paying attention to the quality of their flocks. It is expected, therefore, that an annual improvement will henceforth take place in both quality and quantity of the wool exported.

RAILWAY STATISTICS IN SOUTH AUSTRALIA.—There are now 113½ miles of railway at work in the colony. The passenger receipts in 1866 were £38,363, and for goods, £75,739; together, £114,102, showing a deficiency, as compared with the receipts of 1865, which amounted to £133,313; total number of passengers in 1866, 358,362. There are 1,582 miles of telegraph lines, and 58 stations in operation. Receipts in 1866, £17,649 for 131,143 messages, against in 1865, £17,041 for 112,344.

QUEENSLAND.—The demand for labour in Queensland has now so nearly equalled the supply that Government

have resolved to discontinue the various relief camps that have for months past been at work in the vicinity of Brisbane and Ipswich. Manganese is now reckoned among the products of Queensland; two tons have been shipped at Gladstone *en route* for England. The cultivation of cotton is rapidly extending in Queensland. Four years ago the growth of cotton in this colony was considered an interesting experiment, but few persons expected any practical result would follow. In 1862 14,344 pounds of cotton were exported, valued at £1,423, and in 1865 the quantity had augmented to 612 bales, containing 183,680 lbs. of clean cotton, and during the past year a much larger area of ground was put under cultivation, and the total yield is estimated at about 3,000 bales.

Publications Issued.

A HISTORY OF THE MACHINE-WROUGHT HOSIERY AND LACE MANUFACTURES. By William Felkin, F.L.S., F.S.S. (*Longmans*).—The author has done well in putting on record the knowledge which it has taken a lifetime to acquire, a knowledge, too, which scarcely any other man, probably no other man living, possesses. Mr. Felkin has taken advantage of the peculiar opportunities for the acquisition of this knowledge which his long residence in Nottingham has afforded him, and to his industry and capacity for the task the public are indebted for this history of a great staple trade of the country. Mr. Felkin has long been known in connection with the trade of Nottingham; and his efforts in aid of the Exhibition of 1851 are well remembered by all who were engaged in that grand industrial display. He entered the stocking-making business in 1808, and the lace trade in 1819. In each he was called to take an active part, and since 1828 he has occupied a public position in many transactions connected with both until 1864. The knowledge of persons and events thus necessarily acquired, he has often been urged to embody in such a work as the present. He states in his preface that "having been freed from other pressing duties, he has devoted the whole of the seventy-second year of his life to this effort." How laborious has been the task may be judged, when it is borne in mind that it has thrown upon him the giving an account of inventions and patents, which, in numbers and prolixity of specifications, are probably unexampled in any other manufacture, and all of which have had to be investigated. The short notices of these in the patent list issued from the office fills a volume of 1,070 pp. Mr. Felkin's work traces the progress of the machine-wrought hosiery and lace trade from Wm. Lee downwards through Strutt, Heathcote, and a host of others, both foreign and native, who have from time to time added invention after invention, until the perfection to which the manufacture has arrived is little short of miraculous. There is one curious feature in the history of these inventions, viz., that, with the exception of Lee and Strutt, every one of the many English inventors was a working handicraftsman. As regards machine-made lace, it is stated that such is the excellence at which it has now arrived, that certain descriptions defy the keenest observer to distinguish it from the hand-made article. The work is comprised in a goodly octavo volume of 560 pages, and is largely illustrated with wood engravings and lace patterns. It not only enters into the history of the various inventions connected with the manufacture, but treats at length of the social and economic conditions affecting the trade at home and abroad, and furnishes copious statistics of its progress and present position.

Notes.

PRESERVATION OF MILK.—Gay-Lussac has proved that milk kept from the air is preserved for a long time

perfectly good. Profiting from this experience, M. Mabrun warms milk in a moderate temperature in a tin vessel, furnished with a tube of lead, to expel the air; then the tube is compressed, and the orifice is closed with solder. When the milk is used at the end of several months, it will be found desirable to stir up with it the cream which is formed on the upper part of the liquid. M. Mabrun, having laid this process before the Academy of Sciences for their examination, the committee report that milk thus preserved after six months still possesses all the properties of fresh milk. A prize of 1,500 francs has been awarded to M. Mabrun.

NICOTINE IN TOBACCO.—A Belgian chemist, M. Melsens, who has made numerous communications to the Academy of Sciences, has found that the proportion of nicotine contained in different species of tobacco varies much according to where it is produced. The tobacco grown in France, especially that from the department of Lot, contains about 7·96, or near 8 per cent. of nicotine, whilst from Havannah tobacco only 2 per cent. is found. M. Melsens proposes to smokers, to preserve them from the baneful effects of this alkaloid, to put in the barrel of their pipe or in the cigar-holder a little plug of cotton, impregnated with a mixture of tannic and citric acids. The smoke passing through cotton leaves the nicotine, which combines with the two acids to form tannate and citrate.

PARIS EXHIBITION.—VISITS OF TEACHERS.—The following minute has been recently passed by the Committee of Council on Education:—1. In accordance with the practice of the Science and Art Department at the International Exhibitions at Paris in 1855 and in London in 1862, my lords think it desirable to offer encouragement to the masters teaching in schools of science and art to visit the present International Exhibition at Paris, with the view of studying those objects which may be likely to benefit the instruction given in such schools. 2. Their lordships therefore announce to the certificated masters now engaged in giving instruction in schools of science and art connected with the department, that they will pay to each such master or mistress visiting the Paris Exhibition, the sum of five pounds in aid of their expenses, and to each an additional sum of two pounds for any report, or any useful suggestions which any such teacher may make (in respect to his or her duties or teaching) derived from the study of the Exhibition, such report having first been published in any journal, local or otherwise, and afterwards approved by their lordships. 3. And, further, to each of the three best of such reports referring to instruction in science, and to each of the three best reports referring to art, my lords will give respectively the following prizes in addition to the sum above named, namely,—for Science, for the best report, twenty pounds; for the second best report, fifteen pounds; and for the third best report, ten pounds; and the same sums respectively to the three best reports for Art.

MEETINGS FOR THE ENSUING WEEK.

Journal of the Society of Arts.

FRIDAY, MAY 10, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

MAY 15.—“On New Machinery for Cutting, Tunneling, Quarrying, and Facing Slate, Stone, and Marbles.” By W. FOTHERGILL COOKE, Esq.

MAY 22, Derby-day.—No meeting.

CANTOR LECTURES.

The concluding lectures of Mr. CHAFFERS' course, “On Pottery and Porcelain,” will be delivered as follows:—

LECTURE VI.—MONDAY, MAY 13TH.

ENGLISH POTTERY.—Fulham—Lambeth—Yorkshire—Shropshire—Liverpool—Staffordshire—Etruria—Wedgwood's Wares, &c.

LECTURE VII.—MONDAY, MAY 20TH.

ENGLISH PORCELAIN.—Bow—Chelsea—Derby—Worcester—Liverpool—Wales—Plymouth—Bristol—Lewestoft—and other Manufactories—Battersea Enamel, &c.

The lectures commence at eight o'clock, and are open to members, each of whom has the privilege of introducing one friend.

CONVERSAZIONE.

The Council have arranged for a Conversazione on Thursday evening, the 23rd May, at the South Kensington Museum, cards for which will shortly be issued.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object. The following gentlemen constitute the Committee:—

Rt. Hon. C. B. Adderley, M.P.
J. W. Aitken.
Edward Akroyd, M.P., *Vice-Pres.*
Sir Wm. G. Armstrong, C.B.
J. S. Ayrton, M.P.
J. A. Beaumont.
John Bell, *Memb. of Council.*
Professor Bentley, *Memb. of Council.*
Lord Berners, *Vice-Pres.*
Hon. and Rev. S. Best.
J. Robertson Blaine, *Memb. of Council.*
V. H. Bodkin (Assistant-Judge), *Vice-Pres.*

Sir J. P. Boileau, Bart., *Vice-Pres.*
R. K. Bowley.
Antonio Brady.
Rt. Hon. H. A. Bruce, M.P.
Decimus Burton.
C. Buxton, M.P.
The Earl of Caithness, *Vice-Pres.*
Lord Eustace Cecil, M.P.
R. L. Chance.
Harry Chester, *Vice-Pres.*
The Masters of the City Companies.
Henry Cole, C.B., *Vice-Pres.*
Robt. Coningsby.

Rt. Hon. W. Cowper, M.P.
Sir Francis Crossley, Bart., M.P.
J. Bailey Denton, *Memb. of Council.*
Lord de l'Isle and Dudley, *Vice-Pres.*
The Duke of Devonshire.
Charles Dickens.
James Easton, *Memb. of Council.*
C. W. Eborall.
Lord Ebury.
Lord Elcho, M.P.
William Fairbairn, F.R.S.
Professor Fawcett, M.P.
Peter Graham, *Memb. of Council.*
The Earl Granville, K.G., F.R.S., *Vice-Pres.*
The Earl Grosvenor.
Mr. Hansard.
G. W. Hastings.
Wm. Hawes, F.G.S., *Vice-Pres.*
J. Pope Hennessy.
Sir Rowland Hill, K.C.B.
Chandos Wren Hoskyns, *Vice-Pres.*
T. Hughes, M.P.
Blanchard Jerrold.
Rev. C. Kingsley.
Hon. A. F. Kinnaird, M.P.
Lord Henry G. Lennox, M.P., *Vice-Pres.*
The Bishop of London.
The Sheriffs of London and Middlesex.
Rt. Hon. Robt. Lowe, M.P.
Lord Lyttelton, *Vice-Pres.*
Archbishop Manning.
Henry Maudslay, *Memb. of Council.*

Rev. F. D. Maurice.
The Lord Mayor.
J. Stuart Mill, M.P.
Rev. Dr. Miller.
The Bishop of Oxford.
J. Slaney Pakington, *Memb. of Council.*
Right Hon. Sir John S. Pakington, Bart., M.P., *Vice-Pres.*
Alderman Sir B. S. Phillips.
Sir Thomas Phillips, Q.C., F.G.S., *Vice-Pres., Chairman of the Council.*
The Duke of Richmond.
Rev. W. Rogers.
The Marquis of Salisbury, K.G., *Vice-Pres.*
Titus Salt.
Sir Francis Sandford, *Vice-Pres.*
Colonel Scott, R.E., *Memb. of Council.*
The Earl of Shaftesbury.
Benjamin Shaw, *Memb. of Council.*
Sir J. P. Kay Shuttleworth, Bart., *Vice-Pres.*
S. Smiles.
Seymour Teulon, *Treasurer.*
Thomas Twining, *Vice-Pres.*
Alderman Waterlow, *Memb. of Council.*
E. W. Watkin, M.P.
G. Watts.
George F. Wilson, F.R.S., *Memb. of Council.*
Vice-Chancellor Sir Wm. Page Wood, F.R.S., *Vice-Pres.*

The Council, on the recommendation of the Committee, have passed the following minute:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government to facilitate the visits of skilled artisans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the

men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

HARVESTING OF CORN IN WET WEATHER.

The Council of the Society of Arts have resolved to offer the Gold Medal of the Society, and a Prize of Fifty Guineas, for the best Essay on the Harvesting of Corn in Wet Seasons.

The first part of such essay—after noticing the various systems at present adopted in damp climates for counteracting the effects of moisture upon cut corn in the field, and for avoiding such exposure in wet seasons by peculiar harvesting processes—should furnish a practical and analytic exposition of the best available means:—

- 1st. Whereby cut corn may be protected from rain in the field.
- 2nd. Whereby standing corn may, in wet seasons, be cut and carried, for drying by artificial process.
- 3rd. Whereby corn so harvested may be dried by means of ventilation, hot air, or other methods; with suggestions for the storage both in the ear and after threshing.
- 4th. Whereby corn, sprouted, or otherwise injured, by wet, may be best treated for grinding or feeding purposes.

The whole to be supplemented by a statement of practical results, and actual cost of each system described; and authenticated estimates of any process proposed for adoption, based upon existing but incomplete experiments.

The above requisitions are given suggestively; not to bind the writer to the order or to limit the treatment of the subject, provided it be kept within the scope of practical experience and utility.

The essays must be sent in to the Secretary of the Society of Arts on or before the 1st of January, 1868.

The Council reserve the power to withhold the whole or part of the prize, in the event of no essay being, in the opinion of the judges, of sufficient merit.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

A meeting of the General Committee on the Food of the People was held on the 11th April. Present—Mr. Benjamin Shaw in the chair: Mr. J. Caird, Mr. Harry Chester, Mr. C. Wra Hoskyns, Lord de L'Isle, Mr. Clare S. Read, M.P., Mr. E. C. Tufnell, and Professor John Wilson.

Professor Wilson laid before the Committee the following information on the subject of bread-food and the nutritive properties of wheat, more especially with reference to a system of grinding and dressing corn and the process of panification which had resulted from the investigations of M. Mège-Mouriés, of Paris. Previously to so doing, Professor Wilson called the attention of the Committee to a diagram of a section of a grain of wheat greatly magnified, showing the disposition of the outer lignous envelopes and the internal cellular tissues in a very distinct manner. Professor Wilson stated that he need not go into the question, which everyone present no doubt understood, as to the different properties of alimentary substances, which might be divided into two classes—one which subserves the plastic purposes of the body, and the other which subserves the respiratory process generally; and that for healthy life these must be had in definite proportions, these proportions being about six of the respiratory aliment to one of the other; wheat, better than any other grain, possesses those two alimentary principles in the proper proportions; consequently wheat has been generally looked upon as the bread corn of all civilized nations; as people progress in civilization they give up the old barley and rye, and employ wheat solely for that purpose. About twelve years ago (1853-54) M. Mège-Mouriés directed his attention to the composition of the grain of wheat, and to the processes of grinding and of panification, and the results he obtained were sufficiently important to form the subject of a report, which was presented to the Academy of Science by M. Chevreul, in 1857. The object of M. Mouriés' investigation was to show the defective knowledge and the waste of material in the ordinary practices of the trade; but, although these were fully proved by his results, there appeared to be trade and other difficulties in the way of its general adoption; for, with the exception of some of the large public establishments in Paris, including the Ecole Polytechnique, the Ecole Normale, and the Lycée St. Louis, where it was carried out with marked success and advantage, no good has practically resulted from the principles he so ably marked out and made known to us. In the summer of 1865, while acting as juror on food substances at the Dublin Exhibition, Professor Wilson's attention was recalled to the subject by an article which was exhibited under the name of "Cerealine," and purported to be a preparation of wheat flour by the process indicated by M. Mège-Mouriés. On examination this preparation replied to the tests in a very satisfactory manner, so much so, indeed, as to induce them to verify them by a determination of the nitrogen it contained. This confirmed the opinion they had previously formed of its food value. On further inquiry he found that a simple mechanical process had been devised in the United States, (where, indeed, the flour exhibited had been prepared) for effecting the most difficult part of M. Mouriés' process—that of decortivating the grain. This renders the operation of preparation so easy and so inexpensive as to make it desirable that attention should again be called to M. Mouriés' process, for, besides being far more philosophical, it unquestionably effects a large saving in a food point of view, as compared with

the ordinary practice of mealing. Before describing M. Mourici's process it may be well, for the purposes of comparison, to give in a few words a rough outline of the ordinary process of grinding, breadmaking, &c. The wheat is taken in its natural state and submitted to the friction of two stones between which it is placed. It is then passed through sieves for the purpose of—1st, separating the bran from the flour; and, 2nd, of separating the finer from the coarser portions of the flour. We thus have three principal divisions; the two latter again are sometimes further separated, and various names—boxings, sharps, &c.—given to them. The bran averages from 14 to 15 per cent. of the whole weight, the relative proportions of the residue vary according to the differences of separation. In examining the composition of the grain of wheat, M. Mège-Mourici found that it was a far more complicated structure than was commonly understood. This structure consists—1st, of an outer covering or epidermis; 2nd, epicarp; 3rd, endocarp; and that these three layers consist chiefly of ligneous tissue, and form the extreme covering or true bran. Together they average from 2 to 3 per cent. of the weight of the wheat. The three outer, or ligneous tissues, are valueless for food. They contain a certain amount of nitrogen, but are indigestible; and are not only valueless as food, but do harm as local irritants. These are distinct from the ordinary bran of the mealing process. Beneath these come, 4th, the "testa," or seed coat proper, which is a distinct cellular tissue of a dark colour, yellow or orange, according to the description of the grain. Next to that comes the embryonic membrane, directly connected with the germ, which indeed it supplies as soon as the vital processes of growth are excited. These two enveloping membranes contain nitrogenous principles in larger proportion than the interior portions of the grain; and as we go from the exterior coverings to the centre and follow the starch granules, the amount of nitrogenous compounds diminishes. The ordinary bran not only consists of the "epidermis," or true bran, but also contains the whole of the nitrogenised tissues enveloping the starch granules, and always a certain proportion of them also. Indeed, it has been found commercially profitable to purchase bran and separate the starch or flour from it; from 5 to 6 per cent. of flour are thus often obtained. As already stated, the ordinary bran averages from 14 to 16 per cent. of the weight of the wheat. It is the same in the case of the potatoe. We throw away a good deal of valuable food in the peeling of potatoes. We ought only to remove the epidermis. Simple experiment shows that.

Mr. READ inquired whether the same remark applied equally to linseed?

Professor WILSON thought that the same law would hold good in all similar vegetable structures. Linseed does not contain starch, but the cells contain oil instead. The nitrogenous compounds do not exist in the starch granules, but they envelop them. As you approach the centre of the wheat grain the starch cells do not contain so much nitrogenous compound as the other tissues. He might further state that the embryonic memb. plays the most important part, both in alimentation and germination. That is the active agent of decomposition during the process of panification. The outer covering of wheat when immersed in water speedily becomes saturated with water, but if Na Cl. (salt) be added, the solution only penetrates so far as this membrane, where it is arrested. These two inner tissues contain nitrogen in large proportions, and envelope the mass of starch cells which form the body of the grain. Ordinary flour is composed entirely of these interior starch cells, the remaining portions of the grain being separated in the shape of bran, and carrying away with them at the same time a proportion—generally 5 or 6 per cent. of the flour also. M. Mourici found that the proportion of nitrogenous compounds in the grain was very unequally

divided; that while in the epidermis proper it was least, it existed in larger proportions in the two next layers than it did in the starch cells or flour of the interior, and, consequently, if we would preserve the maximum food properties of the grain, we must return and combine those two layers with the flour, and not waste them by separation with the bran. In the starch cells or flour too the nitrogen was found to diminish towards the centre of the grain, where it was at its minimum, and where of course the flour, though finer and whiter, has the least nutritive value. This is known practically by the fact that the finest wheat flour will not combine with so large a proportion of water in breadmaking as the second quality will, though it may not be so well known that the cause is due to the smaller proportion of gluten present. It has been found by experiment that the finest flour will not take up more than 20 per cent. of water, known as *pain blanc*; that the second quality will take up 30 per cent., *pain de gruau*; while the third quality, with which a portion of the ordinary bran is always mixed, will take up 40 per cent. *pain bis*. M. Mourici, therefore, recommends that the grain should be merely decorticated previous to grinding, and that the layers of cells, so rich in gluten as the testa and embryo membrane, shall be ground up with the starch cells, and form part of the flour used for bread and other food purposes. The bread thus made absorbs more water, rises from 20 to 30 per cent. more, and is more nutritive as well as digestible. Gluten is the nitrogenous property of the wheat, and by the greater absorption of water by the flour in which it is present, weight for weight of flour there is a gain, in the greater number of loaves produced from a given weight of flour, and that would be the baker's inducement to try this process. It would be at the same time more nutritious, owing to the greater proportion of nitrogenous matter the loaves contain. The loaves will contain more water, but the extra proportion of nitrogenous compounds will counter-balance that. One hundred parts of flour of this sort will make say 140 loaves, whereas 100 parts of the other flour would only make 100, and every one of the 140 would be more nutritious than the other. This process may be said to add 60 per cent. to the nutritive value of the flour, while the bulk is only increased 40 per cent.

Mr. CAIRD inquired whether any difference was found to exist in this respect, according to the description of wheat,—red or white, and that sown in spring and autumn?

Professor WILSON replied, within an extremely limited range; all descriptions being subject to the same laws. There was, no doubt, a difference in the varieties of wheat and soil, and the period of sowing, whether spring or autumn, but the range was too limited to be of the slightest importance. He did not think that was a question which need be considered now. The true bran, according to M. Mourici, consists of only the outer coverings, the ligneous tissues, which represent three to four per cent. of the whole. He was only speaking of the wheat as it is in the market; and as we are told we shall probably require 8,000,000 quarters of foreign wheat, it is a matter of vast importance to utilise the grain to the utmost extent it admits of. There is another point of importance in connexion with M. Mourici's process, in regard to the storage and preservation of wheat. It appears that the outer covering—epidermis—absorbs moisture far more readily than the regular cellular tissues of the inner layers, and this renders the grain more or less liable to mould, and other injuries, unless great care be taken by occasional shifting, &c. If you soak wheat grains in water, you will find that the water is readily absorbed by the outer or ligneous tissues, and when you come to the inner tissue there is no longer the same tendency to absorb, consequently, if you moisten the outside surface, and rub it gently, you will rub these tissues off the grain, and the grain will come out in this shape [producing speci-

mens of decorticated grain]. That is, the absorbent envelopes will be taken off, and nothing will remain but the cellular tissues, and in that state wheat may be kept stored for any length of time without its quality being impaired.

Mr. CHESTER asked if this had been proved by any experiment on a large scale.

Professor WILSON—It has been so stated; but I should not be satisfied without further trial, because a great deal of information on the subject has been taken from American sources. The theory is correct with regard to the keeping properties of wheat, the decortication process needs further proof. On the Continent this question is more important, where they have government stores of wheat to last for twelve months, whereas we have free markets. When the wheat is decorticated it can be kept for years without a chance of mustiness or mould getting on it. He would give the Committee the relative values of these different preparations [referring to samples on the table], assuming that the proportion of nitrogenous compounds determines the nutritive value, and that is what we usually go upon. This sample of true bran or epidermis was taken from a very coarse sample of red wheat, and no doubt it exists in larger proportions than in the finer samples of wheat. The true bran contained 4.571 of nitrogenous compounds, the ordinary bran of the market contained 15.019. These analyses were all carried out last winter in Edinburgh. Of ordinary market flour he got three samples, and made an analysis of each, and he found they contained on an average 9.795 whereas the flour prepared by M. Mouries' process contained 15.672 per cent. of nitrogenous compounds, showing an excess in nutritive value of 60 per cent. over the ordinary flour. The average proportion of bran is 14 to 15 per cent., while by M. Mouries' process it is only from 3 to 4 per cent.; we thus have a result of 10 per cent. addition in weight and 60 per cent. more of nutritive properties than by the old process, and at the same time we deprive the wheat of those portions which render it not so well able to be kept. As he had already stated, wheat, by this process of decortication, has less affinity for moisture, and may be stored with less risk. The flour contains more gluten, absorbs more water in panification, and makes more bread, which retains its freshness. All smut and other dirt from insects or otherwise is removed, and the phosphates as well as gluten are preserved. The gluten obtained in starch manufacture has been utilised by mixing it up into bread with ordinary flour, and thus greatly improving its quality. In this case, the same result is obtained by simply not losing it in the ordinary bran. M. Mouries' plan has, in fact, more nutritive value than the actual whole wheat, because you take away this three or four per cent. of what is no good whatever, and the 96 per cent. left behind contains a higher percentage of nutritive value than the whole wheat does. Thus it appeared to him that M. Mouries' process increases the quantity of food material obtained from wheat by at least 10 per cent., because here we have only four per cent. of valueless matter, while in the ordinary process we have 14 per cent., so that we get an improved quantity of 10 per cent., and when we come to the manufacture of the flour we get an improvement of 60 per cent. upon the value. M. Mouries' flour was found to be equal to 15½, whereas the ordinary flour was equal to only 9½. The grain would weigh heavier, bulk for bulk, after decortication, as it would pack closer, owing to the smoothness of the surface. We find that the nearer wheat assumes the form of a sphere, the heavier it is per bushel, and the specific gravity of the grain is a market test of its quality. Chidham wheat is heavier than Talavera wheat, and yet the latter usually fetches a higher price in the market. A bushel of Talavera wheat weighs about 65 lbs., while the same quantity of Chidham wheat weighs from 65 to 68 lbs. That is determined chiefly by the shape of the particles. No doubt by this

process the shape of the grain is altered, because in wheat in its natural state there is always a little bearded roughness, which, though invisible to the naked eye, exists, and increases the tendency to fermentation when affected by moisture, and also prevents the particles lying so close together; therefore, he should say a bushel of decorticated wheat would weigh 6 lbs. or 6 lbs. heavier than ordinary wheat.

Mr. READ asked what was the commercial value of the epidermis?

Professor WILSON replied *nil*; it was only fit to be put on the manure heap. When given in food it was injurious rather than otherwise, it was so sparingly digestible. If moistened it fermented, and became sour in a few hours. The ordinary bran would not do so; this bran would act as an irritant on the stomach.

Mr. READ—Practically, by this process, you get a reduction of a substance which is of no value whatever as food?

Professor WILSON—Precisely so: whereas the other portions of the bran are of higher food value than the ordinary flour itself.

Mr. READ observed, with regard to the commercial value of the bad portions of the grain. The price of flour for the last ten years averaged 1s. 3d. per stone, while the price of bran was 9d.; therefore, though the latter was lost to the human race, it was not lost to the animal world, because it took the place sometimes of wheat meal when it was cheap relatively to other grain in the feeding of animals.

Professor WILSON—We are now looking to the higher class of animals, viz.—ourselves. Every wise feeder of animals, if he can get bran at a low price, will make use of it.

Mr. CHESTER inquired whether the ligneous portion of the bran was valuable for animals.

Professor WILSON replied that the animal organisation was better adapted for it than our own. They got rid of it easy enough. An animal, out of 14 lbs. of ordinary bran, would appropriate 10 lbs., and 4 lbs. would be expelled in the shape of manure. The ruminating process could not convert this into food value at all. Professor Wilson then proceeded to describe the process of decortication as follows: The wheat, he said, is carried up to the topmost floor, then passing through a screen, or riddle, it falls through a hopper into a long narrow trough which contains water, and is traversed through its length by an Archimedean screw. This carries the wheat slowly along the trough to the discharge end, where it now, in a moistened state, falls down a tube to the unbranning or decortication cylinders. These are formed of cylinders of cast iron, ridged on the interior diameters, and with closed ends. A screw shaft traverses the centre of them, carrying broad arms, or floats, set at an angle diagonal or "aslant" to the face of the cylinder, and with a diameter so much less than that as to cause friction, but to allow the grain to pass without crushing. A rapid rotation is given to this central shaft, and, owing to the angle at which the floats are set, a slight progressive motion is given to the grain. The friction causes a large proportion of the true bran—epidermis, epicarp, &c.,—to be separated, and this is removed as it is separated by a blast driven through the cylinder in a direction contrary to the motion of the shaft, which also has the effect of drying the excess of moisture of the grain. The grain then passes along a spout into a second cylinder, where it undergoes the same process, and finally is carried into the drying chambers, composed of a series of iron troughs, along which it is propelled by screw shafts, a current of warm air being driven along them in an opposite direction. It then, being dry, receives its last friction in the polishing cylinders, where the friction is applied to the surface of the grains themselves, which are left in a dry, smooth, rounded form. As this generates a considerable elevation of temperature, the grain requires to undergo a cooling process before storing or using. This is effected by carrying

it up to the upper floor, and allowing it to fall down inclined planes through a flat shallow shoot, up which a blast of cold air is driven. With regard to the grinding of this prepared wheat, there are some advantages over the old system. In ordinary grinding, Professor Wilson continued, there is always a mechanical difficulty in arranging the stones. The aim of the miller is always to produce the best flour, and he has to grind it in such a manner as not to crush and cake the meal, not to allow it to heat between the stones, but to granulate it perfectly and evenly throughout, giving it the wiry feel characteristic of No. 1 flour. If set too close, or if the stones be dull, the flour cells are crushed rather than granulated; it has a soft, unctuous feel, and is then termed "killed." In that state it never mixes well, will never work up properly, or rise well in the oven. If the stones be too keen or sharp they are apt to shave and cut up the bran into fine scales, which speck the flour. Therefore, the successful miller has to steer between dull bran with deadness and sharp bran with speckiness. By this process the true bran (epidermis) is all removed, and the stones have to act on a gluten surface and not on the bran, and consequently the latter risk is avoided. In baking, care should be taken not let the dough stand too long, as is frequently done, and not to have the oven too hot at starting. The bread rises 25 to 30 per cent. more than when made with the ordinary flour, and if the heat is too great at first the crust hardens, and the panification forces the loaf out of shape. This process adds at least 10 per cent. to the weight of the food portion of wheat, while it increases the nutritive value of the flour about 60 per cent. These proportions in all probability admit of some modification, as the flour and the bran of the ordinary process of mealing were obtained in the market, while the flour and bran of M. Mourici's process were, no doubt, obtained from a finer description of wheat than that grown in our climate. This, upon the wheat consumption of the kingdom—say, 20,000,000 of quarters—is a matter of considerable importance. By this process you get a large increase of food value, but you do not get the white bread which is so universally eaten in this country.

Mr. CHURCHMAN inquired whether Professor Wilson could give any practical suggestion to the Committee whereby the process could be brought into notice, and whether he was aware of any public establishment, in any part of the country, where, on the advantages of the process being demonstrated, it was possible a trial of it might be induced?

Professor Wilson replied that he was not prepared with any suggestion at the moment. It was hardly a matter for private enterprise. It was a matter which might be represented to the Government or the Poor-law Board. There was no gainsaying the advantages that were derived from the process; and it might be put to them whether it was worth their while to direct a trial of it in some of the poorhouse establishments. The decorticating machinery would not be very expensive. In the first instance public prejudice to this flour would have to be overcome; he feared that it would take some time to bring the flour into favour with the lower classes, who have a proverbial preference for very white flour.

Mr. WREN HOSKYNs inquired whether flour prepared by this process was cheaper than the ordinary fine flour?

Professor Wilson replied of course it would be, because ten per cent. increase in the quantity would more than cover the expense of the manufacture; but he rather looked upon it as the improvement in nutritive value. As he had already stated, it was computed that we should require this year foreign supplies amounting to eight millions of quarters of corn, whereas five millions of quarters treated by M. Mourici's process would be equal in food-value to eight millions treated in the ordinary way. He added that he was thoroughly satisfied with the philosophy of the subject that it was sound, and it was owing to the circumstance of his acting as a juror on

food substances at the Dublin Exhibition that his attention was called to it by seeing some of this article, the value of which the Americans were keen enough to recognise.

CANTOR LECTURES.

"ON MUSIC AND MUSICAL INSTRUMENTS." By JOHN HULLAH, Esq.

LECTURE VIII.—MONDAY, MAY 6.

MODERN INSTRUMENTS, CHAMBER AND ORCHESTRAL.

Mr. Hullah concluded his (extended) course of lectures on Monday, the 6th inst. The last three, he reminded his audience, had been devoted to the construction and history of musical instruments. It had been seen that all modes of producing musical sound but one—the abrasion or friction of strings—were very ancient, and that every material now used in the making of instruments had been used from the earliest times. The material last applied to the production of sound—hair—had proved incomparably the most important; without the bow, music such as we now have would never have been conceived, nor could it have been executed if it had been. It must not be thought, however, that all ancient instruments were identical in size and shape with their present representatives. On the contrary, these latter had been the subjects of unceasing experiment and repeated change, down to certain epochs at which, for a time, these sizes and shapes had been fixed, by being reconciled with some natural law, by their real or apparent perfection, or by the composition for them of music in such quantity and of such merit as to ensure them against such further modification as would interfere with the execution of that music. In the last lecture it had been shown that the key-board of the 14th century could not have been essentially different in its proportions from the key-board of to-day, unless it could also be shown that the human hand had undergone some great modification. So with the holes of the flute or oboe, the strings of the harp, the frets of the guitar, all of which must be brought within easy reach of fingers of average length. But instruments may easily satisfy this condition and still be far from perfection; and, until any serious inconveniences attending their use could be overcome, it was not likely that they would inspire those who wrote for them with fresh or beautiful thoughts. The instrument has of necessity always preceded the performer, and the performer the music for the instrument; otherwise, the production of good vocal music would not have anticipated by so many generations that of instrumental. Musical instruments have decreased in number as they have improved in quality. As the performers on those of the same species have attained greater skill, the necessity for so many and such slight varieties of them has become less. The oboe and the bassoon represent, in the modern orchestra, a large number of ancient instruments of like construction; and the chest of viols of the 17th century has been replaced by the violin, the viola, and the violoncello, all of which have been extended in compass as well as in general capability. In the race of improvement the bowed instruments, the last to come into the field, have taken and kept the lead. They have also given birth to the earliest great players, and the earliest good instrumental music—evidence, which can need no commentary, of their supremacy in quality, flexibility, and power of expression. The time and place of birth of the first violin proper is still a matter of doubt. The makers of bowed instruments, in the 16th and even in the 17th centuries, did not limit the exercise of their skill exclusively to them, still less to any particular specimens of them. They made viols of all shapes and sizes, long after they had begun to make real violins; and not only these, but guitars, harps, and lutes. So little was the supremacy of the violin recognised, that the makers of stringed

instruments took their name from one now almost extinct—the lute. To this day a continental violin maker is called a *luthier*. The question of the origin of the violin had been complicated by the practice of refitting old viols with new finger-boards, and stringing them afresh. Who made the first violin proper is a question likely to remain without a satisfactory answer; but that it was made somewhere in the north of Italy, and at some time in the second half of the 16th century, is pretty certain. During the first half of that century many excellent luthiers flourished in the north of Italy. One, a native of the Italian Tyrol—Duiffoprugar, set up in Bologna in 1510. Some violins and violas extant bear his name, but closer examination has proved them to be altered and refitted viols. A little later many luthiers settled in Brescia; so many, indeed, that the school of Brescia soon attained an individual reputation. Indeed, it is likely that the violin proper is a native of Brescia,—not less renowned for *virtus* than *virtù*, for no city has contributed, by the valour of its citizens, more effectually to the recent recovery by Italy of a place among nations than Brescia. In Brescia lived, from 1560 to 1610, the celebrated Gasparo di Salò; and, a little later, Magini, a native of Brescia. But the School of Brescia is most renowned for its pupils and offshoots; since Andrea Amati was one of the former, and the school of Cremona one of the latter. Through the labours of this ingenious artist, his sons, Geronimo and Antonio, his grandson, Nicolo, his great-grandson, another Geronimo, and his and their pupils, Guarnerius and Straduarus, Cremona and the violin became literally interchangeable terms. During a great part of the 17th century, notwithstanding the now uncontested superiority of the violin, the viol family still maintained a certain position in the musical world; but towards the end of the century that position ceased to be tenable; and from that time composers and performers have worked exclusively for and with the perfect instruments which already were, and indeed had long been, at their disposal. The violin, viola, and violoncello—varieties in size only of the same instrument—have replaced the whole tribe of viole da braccio and da gamba; and to them has been added a still larger and deeper instrument, the contra-basso or double bass, which again has replaced the violone. From the identity of form of these instruments results a similarity of quality highly favourable to their combination; and this, added to their capability of perfect intonation, approximates them more closely than any other species of instrument to the human voice. No doubt their predecessors, the viols, were often played in tune, and often sounded homogeneous. The superiority of the modern violin lies in its power, quality, and flexibility, which are due to its outline, proportions, and material, to the smaller number, greater thickness, and increased tension of its strings, and to the different form and greater strength of the bow applied to them. The increased arch of the bridge (combined with the *échancrures*), while it has made the violin less available as an instrument of harmony than most of its predecessors, has given it a power and a freedom as an instrument of melody to which none of them could lay claim. In fact, the violin family seems to have attained, in the second half of the 16th century, a perfection beyond which it would seem undesirable and impossible to carry it. The modern orchestra includes all the most important varieties of the two great tribes of instruments—wind and stringed. The violin family represents almost exclusively the latter tribe. The wind instruments are of two species, those of wood and those of brass; and of each of these there are several varieties. Of the wood instruments, the flute only is a simple pipe; the clarinet, oboe, and bassoon being reed instruments. Of the brass instruments, the trumpet and horn are, in their simplest form, mere tubes, the scales of which are limited to the notes of the harmonic chord. The trombone differs from the trumpet and horn, not only in quality but in mechanism.

the length of which is capable of considerable extension. The slide by which this is effected has been of late years applied to the trumpet; and valves, answering a like purpose, have been also applied to the horn. Both these inventions, however, though they afford great facility to the performer, take something from the resonance of the instruments; and their adoption has considerably altered their quality, and is gradually altering the character of the passages written for them. None of these instruments can yet be said to have attained to the status of the violin family. Perfect intonation upon them seems only attainable by persons specially gifted. So difficult is it to the clarinet player, that he is always provided with three instruments, which he uses in their turn for different scales and sets of scales. Considerable inconveniences result from this multiplication of instruments, the most important of which is the impossibility of keeping them at the same temperature, and therefore at the same pitch. This particular inconvenience is limited to the clarinet. One flute, one oboe, and one bassoon are severally used for all keys. In intonation the flute, the most popular and easiest of those instruments, is the most often in fault. The short-comings of the clarinet, oboe, and bassoon, are of another kind, relating rather to quality than to pitch. Performance on every instrument requires or is facilitated by some special physical gift of hand or lip. It is difficult enough for some persons, under the most favourable circumstances, to become good performers on the violin or pianoforte; but success on some wind instruments seems to be attainable by only a few. The trumpet proper has all but disappeared from the modern orchestra, solely on account of the difficulty of blowing it. The instruments on which trumpet parts are now commonly played are not trumpets proper, but composite, hybrid instruments, much easier to blow, and immeasurably inferior in quality. A lip strong and sensitive enough successfully to cope with the difficulties of this instrument seems to be as rare as the conformation which results in a fine tenor voice. This seemed the place, Mr. Hullah said, to speak of the qualities needed to make a thoroughly good orchestral performer—an expression which must be understood to represent a good executant, and a good deal besides. The fable of the bundle of sticks has no application to an orchestra, which is good, bad, or indifferent, in proportion to the number it contains of good, bad, or indifferent players. On some players rests a smaller weight of responsibility than on others, but all are called upon for the exercise of excessive vigilance. The stringed-instrument parts in an orchestra are severally performed by many players. Occasional relaxations of attention on the part of individuals among them may, therefore, do little harm, and escape notice. At the same time, no player in an orchestra, however large, can make a decided mistake without its being heard, and without half his collaborators knowing who makes it. But the wind instrument parts are all individual; no two performers play the same part. The second performer in each case, often playing from the same book as the first, may sometimes rely upon the latter; but the first performer on each pair of instruments is entirely dependent on his own presence of mind and power of attention. In the course of an oratorio or opera of average length, there are often some hundreds of changes of time or key, or both, and within the limits of each of these innumerable pauses, *ralentandos*, *accelerandos*, and sustained notes, the duration of which were subject to the will of singers, not at all bound to execute the same passage twice alike. Sometimes a particular instrument is silent during a movement, or two or three successive movements. Throughout these, unless the player knows the work well, he must count his bars of silence, that he may be prepared for re-entry, often, at some critical point, the missing of which, by an instant of time, would turn the harmony to which he should contribute to hopeless discord, and bring a thousand

excretions on his devoted head. With one eye on his music, the other on the conductor's baton, and his ears everywhere, the attention of the orchestral performer is often exercised without a moment's intermission during a performance lasting for three or four hours. A history of the orchestra would no doubt make an interesting book, certainly a large one, could the material for it be got together, which it is not likely that it ever will. Stories have come down to us, which have evidently lost nothing in the telling, of vast gatherings of vocal and instrumental performers in very distant times; but how these were composed, what proportions the instruments bore in numbers one to another, how the performers were made to work together, what sort of music they performed, all these are questions which will doubtless often be asked, with little chance of their ever being answered satisfactorily. It is pretty certain that a Greek orchestra was limited to the production of melody in unison or in the octave, accompanied by an occasional fourth or fifth above or below it, and, in passages of great intensity, by drums, cymbals, and other one-noted instrument of percussion. But the history of other arts does not justify our assuming that the music of every people, cotemporary with or anterior to the Greeks, was of the same nature as theirs. Mr. Hullah had touched on this point before, but it was so important that he would venture to repeat what he had already said. The Greeks took their arts, in the first instance, from peoples older in civilisation than themselves. They of course rejected what they found distasteful and antipathetic. Their tastes and sympathies went all in the direction of the simple and the clear; and their all but exclusive use of melody no more proves that harmony was unknown to the Assyrians, the Hebrews, or the Egyptians, than does the exclusive use of the lintel in Greek architecture prove that the arch was unknown to their predecessors or contemporaries. We know not much more about the orchestras of the middle ages than about the orchestras of a higher antiquity. We have ascertained, from sculpture and painting chiefly, what the mediæval instruments were to the eye, which enables us to form a very fair estimate of what they were to the ear. But how they were grouped, and what effect resulted from their grouping, are still matters for speculation. The 14th century seems to be the epoch at which musical gatherings systematically organised began to be numerous and important enough to deserve recording. One of the most remarkable was in the year 1341, when Petrarch was crowned in the Roman Capitol. At the ceremony were present two bands of musicians, the one vocal and the other instrumental, who continually sang and played "in sweet harmony" (*con dolce concerto*). Boccaccio's party of ladies and gentlemen, to whose retreat from Florence during the plague in the same century we owe the *Decameron*, are described as continually singing and playing on different instruments. Those mentioned are the lute and the viol, on which latter several of the ladies performed, and the cembalo, probably some kind of spinet. But one of the earliest orchestras of which we have any satisfactory account, and of which the parts were expressly written for the instrument, was that employed in Peris' opera "Euridice," performed at Florence in 1600, at the marriage of Henri IV. of France and Marie de Medicis. The orchestra presents a striking contrast with those of Italian operas of the present day. It consisted of four instruments, a harpsicord, a large guitar, a viol da gamba, and a lute. Seven years later Monteverde produced his opera "Orfeo," in which he employed an orchestra of thirteen different instruments, some multiplied by two or more, so that the number of performers amounted to thirty-six. These were never all employed simultaneously, but only in groups of two or three,—on one occasion only of ten. Among the instruments are mentioned *due violini piccoli alla Francese*—possibly violins proper, but more probably kits. From this time, the beginning of the 17th century, the development of

the orchestra continued, however slowly, with little intermission. In the second half of it orchestras of respectable size were formed, in France under Lulli, in Italy under Corelli, and in England under Purcell and his contemporaries. At the beginning of the last century orchestral composition and performance received a great impulse in Italy from the foundation of the School of Naples by Alessandro Scarlatti, and in Germany through the genius and industry of Bernhard Keiser, director of the opera at Hamburg. With the early days of Joseph Haydn (b. 1732) the history of pure instrumental music really begins, and from them it must be read chiefly in the lives and works of his countrymen. Among these the first place must be given to Mozart. Prodigious as the steps may be which subsequent masters—Beethoven for instance—have made in the development of the orchestra, one particular step of Mozart exceeds them in extent and in importance. In the opera "Idomeneo," produced at Munich in 1780, the modern orchestra was definitely formed, and in that work may be found, by those who know how to seek them, the principal canons by which orchestral composers have on the whole been guided for the last eighty-seven years. Great progress had been made in orchestral effects since 1780, by Mozart himself, no less than by his successors; but the progress had been in directions first taken by Mozart, and the chart of which is the score of "Idomeneo." Mr. Hullah then proceeded, aided by a diagram, to explain the compass and other peculiarities of the various instruments used in the modern orchestra, their proportions as to numbers one to another, with other particulars as to the modes in which they were used. The lecturer proceeded then to speak of those domestic substitutes for the orchestra—the pianoforte and its predecessors. The latter—the plucked keyed instruments—flourished from the 14th century down to the end of the last, in the early part of which the idea of bringing hammers to act upon strings by the key-board occurred to three ingenious artists—Marius, a Frenchman; Schröter, a German; and Cristofali, an Italian. To the latter belonged, beyond doubt, the honour, or the good luck, of having first made his invention known,—in the year 1711. Mr. Hullah then called attention to an instrument in the room, of a class of which the majority of his audience had probably met with few or no specimens. It was a harpsichord (date 1623), made by the celebrated Rucker, of Antwerp, and perhaps one of the most perfect in existence. It had two rows of keys, which afforded the only variety in intensity of which it was capable. It was in consequence of this possible variety that its successor was distinguished as the piano-forte, *i.e.*, the soft or loud. In the harpsichord the string was plucked or pulled by a quill, and unless the key which acted on it was struck very decidedly it produced no sound, while a too hard blow produced no more, but would make a disagreeable rattling. Mr. Hullah then further explained the mechanism of the instrument, the quality of which would appear to those who had never heard it before somewhat thin and wiry; but, perhaps, after listening to it for a few moments they would find that, however inferior in some respects it might be to the pianoforte, it was not without a charm of its own. The lecturer then played a movement from a fantasia by C. P. Emanuel Bach, a gavotte by Padre Martini, and Handel's "Harmonious Blacksmith," concluding, at the request of the chairman, with "God Save the Queen."

The Chairman (Mr Hawes), said that as this was the last lecture of a course which he believed had given especial pleasure to a numerous audience, he thought they would be glad that he should take this opportunity of thanking Mr. Hullah for the valuable information he had conveyed to them, in a most agreeable form. The art of music was one that now excited so general an interest, and was so widely cultivated, that he thought the favourable manner in which these lectures had been received would probably induce the Council to take up,

in future sessions, this and other subjects which were not only interesting to the members themselves, but also to the ladies, who, he was happy to see, formed an unusually large proportion of the audience during the course just concluded.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 8th, 1867; JOHN MACGREGOR, Esq., in the Chair.

The following candidate was proposed for election as a member of the Society:—

Davidson, James, Laboratory Department, Royal Arsenal, Woolwich, S.E.

The following candidates were balloted for, and duly elected members of the Society:—

Ainslie, Montague, Grizedale, Hawkshead, Windermere.
Amhurst, W. Amhurst T., Didlington-hall, Brandon, Norfolk.

Essell, George, The Precincts, Rochester.

Fisher, Thomas, 24, Hanway-street, W.

Hutton, Thomas Winder, 5 and 6, Newgate-street, E.C.

Maddick, Alfred, 40, Clarges-street, Piccadilly, W.

Rylands, Peter, Bewsey-house, Warrington.

Sayer, Commander George, R.N., Statenborough-house, Sandwich.

Tinne, John A., F.R.G.S., Brierley, Aigburth, near Liverpool.

Toler, Hon. Ottway Fortiasque, 6, Albemarle-street, W.

Weld-Blundell, T., Ince-Blundell-hall, Great Crosby, Liverpool.

The Paper read was—

RECENT INVENTIONS IN MILITARY BREECH-LOADING SMALL ARMS IN EUROPE AND AMERICA, PARTICULARLY IN THE UNITED KINGDOM AND THE UNITED STATES.

By CAPT. O'HEA, LATE 25TH REGT., K.O.B.

By the term "recent inventions," I mean to convey that, as far as it is possible for the explanation of such a subject, it is my intention to confine my remarks this evening chiefly to fire-arms invented within the past seven or eight years. It is a proverb that, "Beneath the sun there is nothing new," and this, in a particular manner, appears to apply to breech-loading fire-arms, as we find in the armories of the Tower of London and of Woolwich breech or chamber-loading and repeating guns bearing dates as far back as the middle of the sixteenth century; but I shall leave to the curious in such matters the enjoyment of a dive into rusty antiquity for complex and cumbrous inventions of past ages, and, with your permission, proceed to discuss the ingeniously contrived, smoothly-working, and more deadly weapon of the present day.

To enable you to understand more easily the principal advantages and mechanism of the several breech-loading arms which I shall have the honour to bring to your notice this evening, it is necessary that I should preface my paper with some remarks on the cartridges suited to, and in use with, the arms. The metallic cartridge is the one to which, in particular, I wish to ask your attention; indeed, the invention of paramount value, appears to me to be this cartridge, for the arms can only be remarkable as very ingenious pieces of machinery for carrying out that invention.

A cartridge containing its own ignition is by no means a recent discovery, for, in 1831, Monsieur Robert invented or patented such a cartridge, and in 1836 a Parisian, named Lefaucheur, introduced the metallic cartridge at present, with various modifications,

general use, with smooth-bore sporting arms, and which answers well the purpose for which it is intended.

The cartridge for the Prussian needle-gun, which, although not metallic, contains its own ignition, has been in use in the Prussian service many years. But the metallic cartridge for weapons of war was first largely adopted by the Federal army during the late civil war in America, and was the parent of many beautiful inventions in breech-loading small-arms. There cannot, I think, be a doubt but that to the adoption of this cartridge and the weapons it called forth, may, in a good measure, be attributed the closing of the great civil war of modern times, and the terminating of vast sacrifices of human life and of treasure.

For the purpose of explaining the important connection of the cartridge with the breech-loader of the present day, I will select for description from the many kinds now in use, four—

1st. According to date of invention or patent, is the rim fire copper-cased cartridge in general use in the United States for the past seven years.

2nd. The Boxer cartridge, recently adopted in our own service for use with the Snider breech-loading rifle.

3rd. The Chassepot cartridge, adopted in the French service for use with the Chassepot gun.

4th. The cartridge recently invented by Mr. Dev., of Threadneedle-street.

The first-named (American) is a simple metallic cartridge, consisting of four parts, viz., the shell, the fulminate, the charge of gunpowder, and the bullet. The shell is formed of one description, and from one piece of soft metal (copper),—is without joining or welding of any kind, being punched, or plugged out from the solid metal by machinery, and is as nearly as possible of equal substance or thickness throughout for the purpose of equal expansion. The means of ignition is in the shell, round the rim at the base, and, when loaded with the charge of gunpowder, this shell is made to grip the projectile, so as to unite it with the gunpowder and fulminate in one compact body. The projectile is solid, and composed altogether of lead. In addition to the small number of its component parts, this cartridge has much to recommend it. It is impervious to moisture, and may even be used after immersion in water. It is gas-tight, for the shell, expanding with the combustion of the charge, combined with the resistance offered by the initial movement of the bullet, completely seals the breech, and thus effectually prevents gas escape breechwards. It has the additional advantage that the copper shell can be re-formed and re-loaded after the contents have been discharged. A very portable and simple machine for this purpose is in use in the United States. I see that an instrument for closing and re-priming cartridge cases was patented in England on the 17th April, 1867, by a Mr. Thomas Horsby.

The original shape of this (the American) cartridge case was cylindrical, with a projection at the base for the fulminate, and to help the extraction of the expanded shell, but some modifications have been brought into use with particular arms, the one most highly spoken of being that of General Roberts, of the United States regular army. The peculiarity of this cartridge is that the cylindrical portion of it, which is larger than the bore of the arm, extends into the barrel but a short distance, when the diameter of the chamber, as well as of the shell, lessens slightly until the latter joins the bullet. The inventor informed me that this greatly facilitates the extraction of the expanded shell, causes more even expansion, and enables the cartridge to contain a somewhat increased charge of gunpowder, which latter is a great recommendation to General Roberts's cartridge, as the defect in all American cartridges is the want of a sufficient charge. I have seldom seen in the United States a charge of powder containing more than 45 or 50 grains used in metallic cartridges for an arm of 45 or 50 calibre, to propel from 350 to 450 grains of lead, and large the trajectory, or course of the bullet,

so high and the shooting uncertain at ranges exceeding 100 yards.

The Peabody, Cochran, and Hammond rifles are the only American breech-loaders I have seen using a metallic cartridge with a charge of 55 or 60 grains of powder. However, his fault in the American cartridge could easily be rectified. Another peculiarity of American arms using the metallic cartridge I would mention here. The diameter across the base of the projectile used is always greater than that of the bore of the rifle, measuring from land to land or the raised portion of the rifling. Polygonal rifles, such as the Whitworth, are not used in the United States, consequently the bullet is forced to take the grooving as it passes through the barrel. This has its advantages. It is impossible the bullet can strip, avoid striking, or leaving the grooves; and I have seldom heard of fractures.

The second description of cartridge, the Boxer, is known to you all. I will call it a compound metallic, or, though, like the first-named (American cartridge), it consists of but four parts, viz., the shell, the fulminate, the charge of gunpowder, and the projectile, two of whose parts are compound in themselves. The shell, or cartridge-case, is of two distinct kinds of metal, brass and copper, and in three distinct parts, namely, the base, the coil shell, and the cap for fulminate, and the projectile is composed of lead, wood, and clay, good for the centre of the bullet and clay for the expanding plug. The cylindrical portion of the cartridge-case is formed of a little over two turns of very thin sheet brass, which is supposed to be expanded, or rather slightly uncoiled, by the explosion, thereby avoiding the danger of fracture of metal by expansion, and of consequent gas escape, even though the cartridge be used in a chamber somewhat larger than its diameter. The base of the cartridge-case is also of brass, but of much greater substance than the cylindrical portion of it, to which it is welded or soldered, and it has a projection to stop its entering too far into the barrel, as well as to facilitate its extraction.

In the centre of this base-piece is fixed a cap of copper, which contains the means of igniting the charge, and from which the cartridge derives the title, central fire.

For the purpose of retaining in the new projectile although decreased in weight by 50 grains, the length and figure of the old, as also with a view to place the greater weight as far as possible from the centre of rotation, the bullet has a picket of wood running through its centre, halfway from the apex of the cone towards the base. At the base is a cavity, containing an expanding plug of baked earth, which latter is also intended as a support to the sides after expansion.

As was a necessity with the old muzzle-loading arm, the bullet for the present breech-loader is still made smaller than the bore, and depends for expansion into the grooves on the plug of baked clay at the base. This is peculiar, and why retained I cannot say, unless the material of which the barrel is formed (soft iron) renders necessary the avoidance of forcing the bullet through the grooving, thereby causing extreme expansion. I am more disposed to conjecture this to be the cause of the size of the present bullet, from the caution inculcated regarding the care of the barrel, in the "Regulations for Conducting the Musketry Instructions of the Army," under the head "Cleaning Arms," Part IV., pp. 24 and 25. Although the cartridge-case covers the *cannatures* or grooves which contain the lubricant, it does not grip the bullet, merely holding it loosely in its place.

I am not aware that this cartridge-case can be reprimed and charged after being once used. The charge of powder is 75 grains, and the weight of 60 rounds is about 6 lbs.

It would be presumptuous in an humble individual like myself to offer any opinion of the merits and performance of the Boxer cartridge, when the report of so high an authority as the Inspector-General of Musketry

is published on it. I shall therefore give you General Hay's report, than whom there is not in England one more competent to judge of the merits of a rifle or rifle projectile. The report was printed for the information of Parliament and the country on the 22nd February, 1867. It proceeds thus:—

Report of the Shooting of the Snider Breech-loading Long Rifle with the new or No. 3 pattern Cartridges, Bullet weighing 480 Grains.

Hythe, 15th February, 1867.

SIR,—In obedience to the instructions contained in your letter of the 29th ultimo, I have made a trial of the "central fire ball cartridges made up with a shorter, or 480 grains bullet, called pattern III.," with the Snider breech-loading long rifle, and have now the honour to report, for the information of His Royal Highness the Field-Marshal Commanding-in-Chief, that the shooting at 600 yards is equal to, and at 800 yards better than that of the muzzle-loading long Enfield rifle, pattern 1853, with ordinary ammunition, *vide* table as per margin. I would remark, however, that the angle of elevation with the Snider rifle is considerably greater at both distances than the Enfield rifle, pattern 1853, although the bullet is 50 grains lighter. I need hardly observe, that while the curve of the trajectory is considerably increased (a serious defect in a military arm) the penetration, owing to the decrease of momentum of bullets, must be considerably less than with the ordinary muzzle-loading ammunition. In several instances the cartridge case stuck fast, and could not be removed without the ramrod. The rifle fouled considerably, and in one or two instances there was a slight escape of gas, which did not however interfere with the working of the breech-block. I have no doubt that these defects will be easily overcome when the process of manufacture is better understood. The weather has been very unsettled, hence the delay in making the trial in question, and this report consequent thereon.—I have, &c., C. HAY, Inspector-General of Musketry.

With reference to the latter part of this report, I think it right to state that the defects in the cartridge to which the Inspector-General alludes have, I trust, been overcome in process of manufacture, as I have been lately informed, by the well known gun-maker, Mr. Field, of Holborn, that the Snider breech-loading rifle, in the trial of small arms which is at present being carried on by a special commission at Woolwich, is as yet holding an advanced position, being second or third in the competition. Mr. Field has also kindly given me several cartridge cases of this description, which have been used with the Snider breech-loader, and which, as may be seen, exhibit no trace of gas escape.

The cartridge I have named third, the Chassepot, in use with the Chassepot gun, I will designate a semi-metallic cartridge, as the face of the powder case only is protected by metal. It consists of six parts, viz., the priming, the powder case, the powder, the paste board wad, the ball case, and the ball. The priming consists of a copper cap, like the ordinary military percussion cap, but of smaller dimensions. It is formed at the bottom with two holes diametrically opposite each other, intended to give free passage to the charge of powder for the spark or flash, the fulminating powder being placed at the bottom of this cap; a small plug of cloth or wax covers it, so as to protect it from external concussion. The cap is then covered with a thin washer of brass, copper, or other metal, which is pasted upon or attached to paper, for forming the base of the cartridge, and the priming is thus complete. The powder case is formed from a rectangular piece of paper, rolled upon a mandril, and pasted at the edges. When the case is dry, the priming is inserted by a mandril, and the end of the case is then closed and pasted. The case, being thus prepared, the charge of powder is inserted, and is pushed down gently to give rigidity to the car-

tridge.* A pasteboard wad is next placed on the powder, formed with a hole, into which the twisted end of the paper of the case is inserted, the excess paper being cut off. I have adopted the words of the specification.

The ball case is composed of a paper jacket having two folds of paper, pasted and closed at one end only. The ball is of an elongated tapered form, with a flange at the base. After placing the ball in its case this case is connected to the powder case by a string or thread passed round a groove on each case, a slight distance behind the wad. Finally, the cartridge is greased. The price of the cartridge is 60s. per thousand; the price of the rifle is only 70 francs.

4th. According to date of patent, I have chosen the cartridge lately invented by Mr. Daw, of Threadneedle-street, which I shall also call a compound cartridge, and which amongst recent inventions is worthy of special mention, as containing some peculiarities of novel and ingenious description. The cartridge, like the other metallic cartridges I have specified, is composed of four parts, two of which are compound. The bullet, as in the Boxer, has the wooden picket through half its longer axis, and the clay plug in the base for expansion. The shell is also of brass, and in three parts, retaining the copper cap for the fulminate in the centre of the base.

In almost all other respects this cartridge differs materially from the others I have mentioned. It is much shorter than the present service cartridge, and the inventor consequently claims for it great facility of extraction from the regulation arm. The cylindrical portion of the case is composed of a little over one fold of thin metal, which being united is perfectly gas-tight, and, from the slowness of this one fold, of little or no weight, and of great flexibility and toughness. The latter is a marked advantage over stouter metal, as the case, on the ignition of the charge, cannot fail to take the form of the breech or chamber in which it is enclosed, and cannot impede in the least the extraction of the shell after explosion, as the sudden alteration of temperature after the gas leaves the barrel causes a slight contraction of the metallic shell. Mr. Daw informs me that when the breech-block is open, without using the extractor, the cartridge-case can be removed by a puff down the barrel from the muzzle. It is water-proof as well as gas-tight, requiring no paper covering or lubrication, as, in addition to the shell being joined by cement or solder, it grips the bullet closely above the *cannelures* or grooves, and thus the projectile, with the powder and fulminate, are held together in one compact body by the slight shell. The weight of sixty rounds of this cartridge is 5 lbs. 11 oz., the weight of bullet 465 grains, that of shell and fulminate 105 grains, and the charge of gunpowder is 65 grains. I am informed by Mr. Daw, the patentee, that the cost of this ammunition is £4 5s. per thousand.

Besides those I have selected for explanation, there are various other descriptions of metallic and semi-metallic cartridges, each possessing some peculiarity to recommend it. Amongst the American inventions are the Spencer, Peabody, Ball and Lamson's, the Henry, the Cochran, and a multiplicity of others, for our relatives at the other side of the Atlantic appear of late years to have turned their inventive genius in this direction; but, as I have already stated, the propellent force is deficient in all, save a few, for accuracy at ranges beyond 500 yards; the Americans being under the belief, and with good reason, derived from sad experience and actual practice in the field, that rapid fire at short range, when there is little chance of missing the object fired at by troops but partially trained to steadiness in the ranks, is the essential for military, or rather militia and volunteers employed against an enemy.

Of English cartridges there are not such a variety. The same necessity for such inventions, we are

thankful to say, has not existed for calling on English inventive talent. There is one, however, recently invented cartridge, or rather cartridge-case (the latter I regret to say I have not been able to inspect the projectile used with it, or the charged cartridge), which deserves particular mention, not only as a clever contrivance to suit a particular arm, but as a departure from the fashion and manufacture of cartridge-cases in brass folded or punched metallic substance. The inventor is Captain Selwyn, R.N.

You will easily perceive, then, the important part the metallic cartridge has to perform with the breech-loading arm of the present day, acting as it does as a expansive metallic chamber, containing the charge inside the bore, and only requiring a support of sufficient strength to keep it from moving, to ensure its being in perfect check to gas escape breech-wards.

Before closing this part of my paper there are a few suggestions which I would venture to offer on the system of metallic cartridges in general, acquired from some little practical experience.

In the metallic cartridge there appear to me, in addition to the great essential of a sufficient charge of gunpowder for the diameter and length of bore and weight of projectile, five other requisites for ensuring a favorable result or return in the use of the metallic cartridge.

1. That the shell or case be of metal, of such tenacity or substance as will ensure its expanding and contracting, but not fracturing.

2. That the shell be formed of one piece if of soft metal, and of one fold if of harder or medium metal, so that it be gas-tight, limited as to power of, and speed of expansion.

3. That the expansion of different metals being unequal, the insertion in any part of the shell of any fixed piece of metal, or even of a distinct piece of metal of same kind, be avoided, as tending to weaken or fracture it and increase the cost of manufacture; the fulminate ought also to be placed somewhere on the inner surface at the base of the shell, no matter how that surface may be modelled.

4. That the shell grip the bullet so that the cartridge may be impervious to moisture, and that the expansion of the shell may be compulsory or inevitable on the propulsion of the bullet.

5. That the base of the projectile be of such a diameter that it is not only forced to take the grooves as it enters the rifled portion of the barrel, but that all chance of gas escape round the bullet is impossible, and that the latter contain no foreign substance or body that would make it liable to fracture on being driven into the bore, or make the manufacture of it complicated or difficult under any circumstances.

The advantages of central fire over rim ignition which, in theory, are no doubt maintainable, are not found so in practice, at all events at medium or short ranges, to be appreciated, at least at a range where military fire in *liv* would be effective. When it is considered that central fire cartridges, having conical or pointed projectiles, cannot be used with the magazine arms at present known or in use, without positive danger to the person using the arm, and to all standing near him, I am sure you will agree with me in thinking that any theoretical or other advantage the former may possess does not give it equality with the rim-fire metallic cartridge.

I now turn to remark upon the arms suited to the use of the metallic cartridges, which I have endeavored, however imperfectly, to place before you. My object is not to speak of the barrel of the rifle, but I may mention incidentally one or two points, which may not be generally known to ordinary observers, first reminding you that the chief properties of a good fire arm are power, accuracy, and rapidity of loading.

The accuracy of an arm mainly depends on the finish of the bore, and the weight and quality of the metal of the barrel. The greatest accuracy is attained at short and medium ranges, and when the influence of

* This is peculiar, and in the English school would be considered equivalent to loss of range.

the wind and of the atmosphere are but slightly felt, by rifles having equal expansion throughout the barrel—the most perfect barrels being manufactured of metal of equal quality, and having a thickness of such metal all through from breech to muzzle equal to the diameter of the bore. As all reductions of this weight, or lightening of the metal towards the muzzle, unless compensated for by a continued and gradual alteration of the quality of the metal throughout the barrel (which I conceive to be an impossibility), must be at the expense of accuracy, no such certain results can even be attained from a barrel sufficiently light at the muzzle for use with troops.

Upon the quality, and the quantity, to a certain extent, of powder used, depends power. I will, therefore, assume for the present that all small arms are equal in force and accuracy, as they may be made if they are not, and will turn to explain the mechanism of the frame, and the appliances for loading and closing the breech of several fire-arms suited to the use of the metallic cartridges in the foregoing varieties.

To the observant soldier or civilian, acquainted with the use of fire arms and interested in military or other arming, it has long been evident that, not only does the question of efficiency and military success depend upon the end of the barrel which receives the charge, but also upon the use of that arm which can be loaded with the least difficulty and in the shortest space of time.

Assuming, then, that time spent in changing fire arms is time lost, it follows that if we could be so fortunate as to get hold of an arm of simple and durable construction that would require no time to load—in fact, which after each discharge would be found ready loaded for another, leaving all time to aim and fire, we should have a perfect, in fact a magic weapon. Such an arm not being forthcoming in the present day the next best would be the one requiring the least time to load, of course everything else being equal, simplicity of construction, durability, finish, and all other essentials.

That arm which requires the fewest and simplest movements to load it, can be charged in the shortest space of time, but, as we are all instructed, and know well, that aim, to be effective, cannot be limited as to time, leaving the sharp-eyed or quick-fingered volunteer, or the more slow and well-trained regular to fire in his own good time with a snap shot or rising aim, I shall now endeavour to place before you several descriptions of breech-loading small arms, which, for convenience in explanation, I propose to divide into three classes:—

1. Single-loading arms, or breech-loaders simple.
2. Repeating breech-loaders, or magazine arms.
3. Single-loading and repeating arms combined, or compound breech-loaders.

By the first division I mean breech-loaders in which the barrel is charged by hand from the ammunition or expense pouch of the soldier round by round of ammunition. By the second I mean arms containing a magazine from which ammunition, to a certain extent, is supplied to the barrel round by round by mechanical means, and which when exhausted is replenished by the soldier's supply in his pouch. The third division is a combination of the first and second, being a single-loading arm having a magazine in reserve.

Of the first division—single-loading arms or breech-loaders simple—I have some here of English and American manufacture, as also the French arm, the *Chassepot*.

It would be difficult to make a selection from so much that is excellent, were it not necessary that I should follow to some extent the classification I have adopted in the explanation of the cartridges. I will therefore first attract your attention to those single-loading arms suited to the use of the four descriptions of cartridges I have chosen, and afterwards shall be happy to give any explanation in my power regarding others which have been entrusted to me.

The Peabody rifle will worthily represent a single-loading arm, using the copper-cased rim-igniting car-

tridge. It is Yankee in the fullest sense, being a Massachusetts invention, and bearing a name justly honoured in this great city. It is a very simple arm, as you will see, and I understand most effective. Exclusive of the frame, the breech-loading appliances consist of four parts and five pivots. The means of extracting the charged cartridge, or empty shell after explosion, is the simplest and most perfect I have ever seen. It is effected by the action of an elbow lever, which throws it out with unerring certainty the instant the trigger-guard is lowered; and this lever derives its power from the action of the breech-block itself, and cannot become deranged, as it is not dependent upon any springs, and is of such strength as to prevent the possibility of breakage or derangement by any service to which it can be exposed. The rifle cannot be discharged until the breech-block is in its proper position, and when not loaded it cannot be injured in the least by being snapped. It has been reported on by the board of officers appointed by the United States War Department for inspecting small-arms, as being "undeniably the best for the use of troops," their duty being only with reference to an arm for military purposes.

This arm can be loaded in two simple movements, the extractor doing the duty of another motion, as follows:—

1. With the thumb of the right hand close down the guard lever with some force, and the cartridge or shell in the barrel will be immediately thrown out. Carry the hand to the pouch, and take hold of a cartridge with the forefinger and thumb.

2. Place the cartridge into the barrel, pushing it home with the thumb. Close the breech, and the gun is ready to fire, on being cocked.

You are no doubt aware that for this description of cartridge rim-fire the exploding bar, or striker, must be somewhat at one side, not in the centre of the breech-block. The weight of the Peabody long rifle is something less than our regulation arm, its calibre .50. The charge of powder is sixty grains, and the weight of ball is 425 grains.

I have here other varieties of single loading arms adapted to the use of the rim-fire copper cartridge, all of which are American inventions, such as the Cochran, the Jocelyn, and the Hammond.

The Hammond breech-loading rifle, which I received for inspection a few days since, is a novel description of American single loader, and relates to that class of fire-arm in which a solid swinging breech-block is used to open and close the cartridge chamber, and, at the same time, to act on the ejector.

The invention consists, firstly, in making that part of the frame against which this rear portion works of an eccentric form, so that when the breech-block is swung to the left, it will have a lateral and oblique rearward movement, for the purpose of opening the cartridge chamber, and when swung to the right shall have a lateral oblique forward motion to close the cartridge chamber.

The inventor claims for this arm that it has no weak parts, is not liable to get out of order, and may with safety be placed in the hands of raw recruits.

In the limited space of my paper it would be impossible to give a full and detailed description of this or any of the arms I have here, but in this particular one there are a few peculiarities of merit to which I think I ought to attract your attention, viz., that the hammer is made to serve, at the time of firing, to lock or key firmly together the frame and breech-block; also, that it is impossible for it to be snapped until the breech-block is in its place. I have only seen one other American rifle in which a somewhat similar appliance has been adopted, namely, Weasons' patent. I am informed that Mr. Daw has fired this arm, at a trial at Chislehurst, with deliberate aim, ten times in fifty-seven seconds, making at a hundred yards three bulls'-eyes and hitting every round. The weight of the American rim fire cartridge for the Hammond arm is 527 grains. Copper case, not quite 90 grains; ball, 378 grains; powder, 59 grains. Mr. Daw

has converted this rifle into a central fire arm to suit his cartridge, altering the charge of powder to 56 grains.

The representative of the inventor of the Hammond rifle is present this evening, and he or Mr. Daw will give more particular information on the arm, should it be required, during or at the close of the discussion.

The arm for which the second description of cartridge was invented, is the Enfield rifle converted to a breech-loader on the Snider system. Regarding the practice with this arm, I refer to the official report of the Inspector-General of Musketry, already given. To load the Snider two movements are necessary, one of which is compound, having several motions under the head of one order, namely that part of the movement detailed at "Three" of the order "Present," and commencing—"Half cock—open the breech—and, holding the breech-block firmly with the forefinger and thumb, by means of the thumb-piece and nipple-lump, draw it back as far as possible by a jerk, raising the muzzle of the rifle slightly in doing so, to remove the empty cartridge-case; at the same time cant the rifle sharply over to the right, to allow the case to fall out, bringing it again to the horizontal position; then, carry the right hand to the pouch, and take hold of a cartridge at the rim with the forefinger and thumb" (*vide* "Platoon Exercise" for long and short Snider breech-loading rifle). Though this arm may not be as perfect in all respects as some original inventions, it ought to be remembered that it is a convert, and, taking everything into consideration, it is a good arm, and much has been made of the old material. I have seen a few other arms altered to suit the central fire cartridge. I may mention one, the Mayall, which, by the kindness of Mr. Crane, gun-maker, I have been enabled to examine, and which appears a capital conversion.

Of the Chassepot gun, using the Chassepot cartridge, I can say but little from my own experience; it is a needle gun, and the invention consists mainly in the contrivance adopted for preventing the escape of gas breechwards. The hermetic closing of the breech parts is obtained by the instantaneous compression, under the action of the explosion, of a vulcanised caoutchouc washer interposed between the front face of the breech-bolt and a flange, or shoulder, upon the needle-guide, which guide is marble. The washer and the flange, or shoulder, are of a little less diameter than the breech in which they are fitted, so as to facilitate their play therein, but the diameter of the front face of the breech bolt is as nearly as possible equal to the inner diameter of the breech. When the explosion takes place, the pressure transmitted by the movable needle-guide to the washer is such that the latter is compressed sufficiently to hermetically close the rear end of the barrel, and thereby prevent all gas escape. (Those who have noticed Thompson's patent stoppers, used by Messrs. Cross and Blackwell for their pickle bottles or jars, will at once understand how this is effected.) After the charge is fired and the pressure removed, the washer, by virtue of its elasticity, returns to its natural position. The washer is composed of three layers, one over the other, intimately united, and having different degrees of hardness, viz., the two outward layers are of much harder substance than the centre one, so that, on being pressed, the intermediate layer, which is perfectly elastic, expands. The mechanism of the breech consists of seven parts. Any central-fire breech-loader can use Mr. Daw's cartridge.

Of the second class of arms, repeaters, I have here two good specimens, of the performance of which, in actual practice against an enemy, I can speak from some experience, having been in the United States during the latter part of the civil war. The Spencer is a repeater of seven rounds, having the magazine in the stock, between the heel-plate and the breech, which magazine is composed of a double sheathing of metal strongly incased in the wood, and thus presents as formidable an obstacle against external force as does the

barrel itself. It is asserted that the cartridges in the magazine of the Spencer are, if possible, less liable to premature explosion than is a single cartridge of the ordinary kind in the barrel of a muzzle loading arm. There are, however, with all its merits, like everything in this world, two or three weaknesses in the Spencer which I should wish to point out. The magazine spring being a detached part is liable to be lost when loading the magazine, the extractor, which levers out the shell, the cartridge, may be bent or broken, and the cartridge in travelling from the magazine to the chamber sometimes jams; but I am informed that two of these little blemishes are about to be corrected in this most efficient arm. The barrel of the Spencer can be charged from the magazine by the lowering and rising of the guard-lever, another motion being required to cock. The weight of this arm is 10 lbs., the charge of powder is forty-five grains, and the weight of the ball 400 grains.

The other arm of this class which I have here, the American Henry, has a magazine of fifteen rounds, which is situated beneath the barrel and parallel with the bore. The magazine can be filled in thirty seconds, and it is asserted that the gun can be fired from the shoulder fifteen times in ten seconds. The charge of powder 25 grains, and the weight of ball is 216 grains. The great objection in this arm, namely, the magazine being exposed and the necessity of loading it from that end next the muzzle, has been removed in the improved arm, the Winchester Henry. By lowering and raising the guard lever the barrel of this arm is charged with cartridge, the cock at the same time being placed at the bent, by which one motion is saved.

Of the third division, compound breech-loaders, there are two here for examination—Ball and Lamson's repeating and single-loading carbine, and the Spencer, already named, converted into a compound breech-loader. At the commencement of this paper, I quoted the proverb, with reference to fire-arms, that "there was a thing new beneath the sun," but the first-named arm is the exception to prove the rule, for I have never read or heard of an invention with such power. It combines the advantages of a single-loading gun and a repeater being used for either with equal facility. It may be fired as a repeater nine times in eleven seconds, and as a single-loader twenty-five times per minute, so the inventor asserts, and Mr. Lamson has informed me personally of the same. The magazine full of cartridges may be held in reserve for any sudden emergency without using the arm as a single-loader. It may also be emptied of cartridges without firing or detaching any of the parts. If one or more cartridges should be put in the magazine wrong end first, on working the lever every wrong cartridge will be thrown out by the ejector, without interfering with the working of the gun, or causing the removal of any part of it. There can be no explosion of the magazine, as this is securely closed whenever a cartridge enters the barrel; it is entirely covered and protected from accidents. The weight of the carbine is only 7½ lbs., the calibre is .50, the length of the barrel is 22 inches, the charge of powder 45 grains, and the weight of bullet 350 grains.

This little arm is an American monitor on a small scale, for it admonishes you when it is loaded, as you cannot open the breech when there is a cartridge in the barrel without going through the motions of firing, viz., drawing the cock to full bent, and letting it drop again on its bearings, the breech being locked whilst the arm is at half or full cock. It has one other peculiarity I would mention, there is no danger of the firing from rust nor other causes of either pin or striker, as neither one or the other is required, the charge being ignited by a blow on the cartridge case direct from the hammer.

I have often heard repeating arms objected to, on the score that the supply in the magazine would be wasted by the soldier. When looking back at the register of the practice, to use a musketry term, on human targets

f troops but partially disciplined that were armed with his description of weapon, during the late civil war in America, we cannot help looking on this objection as premature. Experience proves that, in the only war where these arms have been tested, the great superiority and advantage the soldier had over the enemy arose from the fact that his having such a weapon in his hand gave him confidence and self-possession, so that the chance of waste of ammunition through excitement was actually diminished.

I will conclude by thanking this assembly for having so patiently listened to my somewhat lengthy paper this evening, which, as can be perceived, has been hastily written; and I trust they will deal lightly, both in thought and word, with its many defects, and any peculiarity of opinion which I may have ventured to intimate.

DISCUSSION.

Mr. NURSEY introduced to the notice of the meeting a specimen of the improved Spencer rifle, to which allusion had been made in the paper, and explained its mechanism. He said that the ordinary Spencer arm could only be used as a magazine rifle. He should not, perhaps, say solely as a magazine gun, because it had been used in America as a single breech-loader, by the magazine being shut off by a piece of string tied tightly to the guard lever, which prevented the magazine being opened; but there was this fault in the original arm, that if the extractor was not very nicely regulated, the cartridge shell jammed, and could not be easily extracted. Mr. Nursey stated that the main peculiarity in the arm was this: the action of the stop consisted in crossing the jaws of the double cartridge guide, which then stopped the breech-block from descending beyond a certain point by coming up against the extractor. Some trials had lately taken place with this rifle in France. In an official trial which took place recently, the firing commenced at 200 metres, and was carried on successively at 400, 600, 700, and finally at 760 metres. Bull's-eyes were repeatedly made by officers who had never fired the gun before. After the practice at 760 metres, the party moved up to 200 metres for the purpose of testing the gun at rapid firing. At this point forty-two shots were fired in two minutes, when the firing was momentarily interrupted owing to the barrel becoming too hot to be held with the naked hand. A thick glove was put on, and thirty more shots were fired at the same rate. As a single-fire gun many shots were fired with great rapidity.

Capt. SELWYN, R.N., said that it was generally allowed that in proportion as perfection in destructive agencies was arrived at, war would become impossible, and it was with that view they studied the question of the best mode of sending projectiles through the air which would destroy life to the greatest extent; although that must be looked upon as a rosewater mode of warfare compared with what had been proposed to be effected by chemical means, as described in a paragraph recently published in the *Standard* and other papers. We were, however, slowly and painfully elaborating the means of firing the greatest number of effective shots against an enemy in the shortest time; but it would be impossible to judge correctly of the merits of the different weapons submitted to them, unless they first of all considered the question—what was a sufficient projectile? The weight of bullet which had been decided to be effective was that which was capable of breaking a horse's leg at 500 yards, and this was found to be 520 grains. Such a bullet ought to be projected to a range 1,000 yards without too high a trajectory. It was well known that a low trajectory was of enormous value in a military weapon. If they took a charge of 50 grains of powder and fired a 520-grain bullet at 1,000 yards, they would have to point the gun almost to the sky. If, on the other hand, the weight of the bullet was diminished,

it would not break a horse's leg at 500 yards; therefore they must adhere to the heavy bullet, and this involved a great amount of propulsive force. The propulsive force generally used with this weight of ball was 70 grains of powder, which was considered sufficient to give satisfactory effects at 1,000 yards. The first attempts with the French rifle were made with 386 grain bullets and 55 grains charge of powder, and the results were, as reported, that "the trajectory was anywhere, and the range nowhere;" thereupon the charge had necessarily been increased, and the weight which the soldier had to carry was something like 6 lbs. for 60 cartridges, or 10 to the pound. Out of that the bullet was 520 or 530 grains, and the powder charge 70 grains; and by no device could they materially reduce the weight of the cartridge if they adhered to the weight of ball he had referred to. If they diminished the weight of the cartridge-box or powder they could only do so to the extent of four or five grains, but if they took only a small piece of the lead there was a sensible reduction in the weight; but they could not do this consistently with efficiency. With regard to any magazine gun, it was only fair, in estimating the rapidity of firing, that the time occupied in filling the magazine should be taken into account; and, moreover, if the gun would not bear the full powder charge, it could only be regarded as a cavalry arm. If there was such a combination of springs and levers that the ordinary soldier could not manage the weapon, it became objectionable on that ground. He urged the meeting not to be run away with by a pretty toy, produced at the expense of simplicity. Neither the storm sands of the East, nor the salt water of the ocean, spared the most ingeniously-contrived springs and levers. Simplicity was the main point. He did not desire to speak of any particular invention, but only on the ground of principles involved in the question; and one most important point was with regard to the construction of the cartridge. They knew very well that at two miles distance an ammunition waggon afforded a target sufficiently large for any rifled field gun to fire a shot into it with certainty, and under these circumstances, if the ammunition was of a character which could be blown up, the resources of an army would disappear from the field before they could be called forth. That it was which led the American Government to decide that they must have metallic cartridges. As to what had been done in the way of metallic cartridges in this country, the Boxer cartridge was described in the paper as consisting of four parts only: he could tell them it consisted of no fewer than fourteen different parts, and of those fourteen parts only about six were absolutely necessary. Now, what did those parts consist of? They were a fold of sheet brass and a base of sheet brass. The original invention consisted principally of these, but, when that sheet brass was tried, it was found that there was expansion at the base, sometimes owing to the thinness of the metal, and sometimes extraction was impossible, therefore a solid piece of brass was added, 74 grains being the total weight of the cartridge. It had, therefore, been necessary to reduce the weight of the bullet at the expense of the utility of the weapon, and the secret of the conflicting reports made to the House of Commons on the efficiency of this cartridge was that in no instance had the same kind of cartridge been used—the powder and bullet charge were constantly varied. Captain O'Hea's very able paper had been one of the first to give them really the different weights of powder charge and bullet fired in the various rifles, and that was the whole measure of the efficiency of a weapon. If it could not carry more than 55 grains of powder it would not do for long ranges; if it would not carry at a low trajectory it would not do for infantry; and if the weight of ammunition was such that a man could not carry it, they might as well not have the means of firing with rapidity. A French gun had been produced to fire a great number of shots, but what was the use of it? Two men could carry the gun but they could not carry

the ammunition. Returning to the question of magazine arms, he recognised the value of the fact that they could be made so as to act both as single loading and magazine arms, but he would ask whether they had been produced of full size for infantry, fit to carry a bayonet? [Captain O'Hea said this was so.] Then the additional weight to be carried was the charges in the magazine, and they must take that into consideration. He had been much gratified by the interesting collection of breech-loading arms which had been brought before them that evening. He had seen larger collections, but none more judiciously chosen, and it required a man who knew his business well to select from a large number the few which were worth something.

Mr. CHERRY expressed his regret that he had not been able to bring with him a Chassepot rifle, owing to the manufacture of that arm being conducted in separate parts at different places. He believed there were only one or two of these rifles in this country at the present time.

Mr. RIGBY (of Dublin), responding to the Chairman's invitation, said, being partly concerned in the invention of the cartridge known as the Boxer cartridge, this was naturally a subject in which he took a considerable interest. There were a great many ingenious contrivances in the American arms that had been brought before them this evening; but, however much our cousins across the water had been before us with their inventions in point of time, he thought the present year was likely to reverse the relative positions of the two countries in that respect; and the competition which our Government had so wisely set on foot would, he was sure, produce a great number of weapons of nearly, if not quite, equal value. We were very apt in this country to bow down to American ingenuity, and to sneer at the talents of our native artisans. He had seen, since his arrival in London a few days ago, several models of arms, some of which had been laid before the Government, which appeared to him the perfection of simplicity, and in that respect were not inferior to any American invention whatever. If he might be allowed he would ask the permission of the Chairman to call upon the inventor to bring before the meeting a weapon which had not been alluded to in the paper, and which was remarkable for simplicity.

Mr. DINES exhibited the rifle alluded to, and explained its parts and action. In this weapon the breech end of the barrel has connected to it a tubular body, forming a continuation of the barrel, the rear end of which is prolonged, in the form of a tang or strap, to receive the breech-pin, which is screwed through the stock from the trigger-guard below. The upper part of the forward end of the tubular body is cut away to admit of a cartridge being inserted into the barrel through the opening so formed. Sliding to and fro within the body is a tubular breech-plug, closed at one end. When the arm is loaded ready for firing, the forward end of the breech-plug closes the end of the barrel. To the rear end of the breech-plug a lever is pin-jointed, the pin being left projecting about the eighth part of an inch beyond the side of the breech-plug, so as to form a stop to prevent the breech-plug being pushed too far forward when the gun is empty. The lever at this time lies in the tang of the body, and the spur, at the end of the lever, passes through the tang, and is held in its position by a catch. Within the tubular breech-plug is a plunger, sliding to and fro. Behind the plunger is a spiral spring, which presses constantly against it. The rear end of this spring bears against the fore part of the lever, so that the plunger is pressed constantly against the forward end of the breech-plug. In front of the plunger is a small projecting piece, which passes through a hole in the forward end of the breech-plug, and acts as a striker to explode a cap in the centre of the base of the cartridge. When the breech piece is drawn back, a tooth on the stem of the plunger is moved back beyond a catch, which re-

tains it. This catch passes through a hole of its own size in the underside of the body, and likewise through a slot in the underside of the breech-plug. It is retained in its position by the spring, which presses it upwards against the body. This catch is connected to the trigger, so that the breech having been closed, the catch may be withdrawn by pulling the trigger, and the plunger thus set free to be driven forward by the spiral spring to explode the cartridge. In order to withdraw the empty cartridge case after the piece has been fired, the forward end of the breech-plug carries on its opposite sides two extractors, which, when the breech is closed, pass beyond the flange on the base of the cartridge case, so that when the breech-plug is drawn back the empty case will be drawn back with it. It is desired to render the arm useless at any time, or to clean the barrel from end to end, it may be done by pulling the trigger well back so as to free the block from the slot in the breech-plug, when the breech-plug may be entirely withdrawn from the rifle. Mr. Dines stated that he had fired 18 rounds in 70 seconds, making six centres and four bull's-eyes at 300 yards, the first time he used it. He had no doubt he should be able to fire 20 rounds in the same time. An important feature in this weapon was that the breech-plug could be readily taken out and carried away, leaving only the barrel and stock behind; so that in case of retreat the weapon could not be used against those by whom it had been abandoned.

Mr. DAW said he first introduced the present central fire system in this country in the year 1861, and had out a patent for it. Since then he had shown its merits in various parts of the world as applied to sporting rifles. Finding that the Government were set upon having metallic cartridges, he had given his attention to the matter for some months past, and he had introduced the cartridge referred to by Captain O'Hea in his paper. This cartridge was 67 grains lighter than the present cartridge known as the Boxer. It was made of the thinnest metal it was possible to get rolled compatible with being water-proof and gas-tight. It was composed of only four parts as compared with the number used in the Woolwich cartridge, and 60 rounds weighed 5 lbs. 12 oz. as compared with the weight of 6 lbs. 8 oz. for the same number of the Woolwich cartridges. With regard to what had fallen from Mr. Rigby, he would state that he had models of cartridge-cases made, under the suggestions of that gentleman, with a coil of brass such as was now used at Woolwich. He expressed his readiness to submit his invention to any public test that might be desired, and his conviction that his plan of manufacture would be a saving to the country of many hundred thousand pounds annually.

Mr. BOTLY, having expressed his admiration of the beautiful inventions and workmanship that had been laid before the meeting, inquired whether, at the rate of firing stated to be accomplished in some instances, the heating of the barrel was not so great that it could not be held in the hand.

Capt. O'HEA replied, after a certain number of rounds the heat of the barrel would become very great, no doubt; that would be after 35 or 40 rounds, according to the thickness of the barrel and the quantity of the metal. From the Henry rifle 30 rounds only could be fired without heating to an extent that it could not be held in the hand; but that had now been entirely remedied by constructing the weapon in such a way that there was no connection between the stock and the parts which heated.

Mr. BLACKIE said, with regard to the number of bull's-eyes stated to have been made in the trials of these weapons with rapid firing, he should be glad to know whether they were made at the commencement, at the middle, or at the latter portion of the firing. As the barrel of the gun became heated in parts, the bore was not the same throughout, because the barrel was not all the same thickness of metal, the thick portion was not heated so soon as the thin, and the thin part thus

became expanded. He thought this was a question which had not been considered, and it was necessary to find out whether the expansion and contraction of the barrel did not render it desirable that the barrel should be of equal thickness of metal throughout the whole length.

Mr. KERR said that with regard to rapidity of firing, 50 rounds might be fired right off if there was sufficient strength of metal to stand it. But he apprehended this great rapidity of firing was not required.

Mr. NEWBY having given a description of the Jocelyn rifle,

Captain O'HEA, in reply upon the discussion, said, with reference to what had been stated by Captain Selwyn, he would give the calculation he made with regard to rapid fire, which he trusted would satisfy the meeting as to the efficacy of these weapons at short range. He did not pretend they were effective at long range. He supposed that troops in line would travel 75 paces in half a minute at "double quick," that would be 36 inches per pace. That was going an extreme distance for a charge. During the time the men were charging they could not fire, nor could they have skirmishers in front to cover them: so that the line which was receiving the charge would have plenty of time to deliver 16 rounds with good aim from these rifles; and if one round in 16, or even in 30, took effect, there would only be left half the number of men who commenced the charge. That was speaking of these weapons at short range.

The CHAIRMAN said he was quite sure the meeting would unite in thanking Captain O'Hea for this exceedingly interesting paper. He would not offer any observations upon it except on two very small points. One was with respect to the name which had been given to a cartridge now in common use, and which was the name of a Government officer. He thought it most unfortunate that a gentleman who from his position was called upon to judge impartially of the inventions of others should be himself an inventor, having personal interests involved which must naturally bias his judgment. The other point was one of a totally different nature. There was a commission for examining the 94 guns sent in for competition to the Government, but so many accidents had taken place in the trials of rifles—especially that lamentable one which occurred to Lord Bury—that a very useful suggestion had been made within the last few days, which would, no doubt, be carried out; that was, that inventors, who might be imagined to have confidence in their own productions, should themselves be called upon to fire the first rounds with their own weapons. He was sure that all present must feel indebted to Captain O'Hea for the very able manner in which he had treated this subject.

A vote of thanks to Captain O'Hea was then passed.

The following account of a trial of the Chassepot rifle, which recently took place before the Emperor of the French and Prince Oscar of Sweden, appeared in the *Times* of the 8th inst.:—"A battalion of the foot chasseurs of the Guard was placed at 600 yards from the mark, and the results obtained were quite extraordinary. After a period of precisely two minutes the trumpet sounded the call to cease firing. It was then found that the battalion, 500 strong, had fired 8,000 balls, of which 1,992 had struck the line of object aimed at. All the ground immediately in front of the mark was cut up by the balls in such a way as not to show a blade of grass left. The Emperor uttered an exclamation which graphically depicts the result, 'It is frightful! it is a positive massacre!' The battalion afterwards executed several times a similar exercise, but at distances increased to 1,000 yards."

Proceedings of Institutions.

HASTINGS MECHANICS' INSTITUTION.—The thirty-fourth annual report to 1st May, 1867, says that a steady, onward movement of quiet usefulness is its chief characteristic; endeavouring to lead on the members to the cultivation of an elevated taste, having in view the primary objects of the Society rather than a pandering to the popular prejudices of the hour. Although the year just passed through has been one of undue commercial depression, the Institution has not materially suffered by it. The number of members is above the average of the last five years. The classes, the lectures, the reading-room are as well frequented as formerly, or even better. Among the lectures that have been delivered during the session may be mentioned one by E. Wheeler, Esq., F.R.A.S., on "Ocean Telegraphs;" one by J. C. Savary, Esq., "Explanations of the System of Examinations in Connection with the Society of Arts;" one by Mr. W. Ransom, on "The Spirit of Philosophical Inquiry;" one by Mr. G. St. Clair, F.G.S., "Curiosities of Light;" one by the Rev. W. Barker, on "Ancient Mythologies;" one by Mr. A. H. Wood, on "Combustibles and Combustion;" one by Elihu Burritt, Esq., on "The Benevolent Associations of the Day;" one by Mr. J. Banks, on "Water Supply, Drainage, &c.;" one by Mr. W. C. Beck, on "Oliver Cromwell." The classes have been in active operation during the winter. There are now in the borough men holding high positions, who are not ashamed to own the class-room of the Institution as the basis from which their upward career commenced. There are sixty-two names on the class list. The following classes are in existence:—Senior French, junior French, arithmetic, drawing, elocution. The committee have again offered prizes for proficiency, and the following gentlemen have acted as examiners:—Mr. Stewart for French; Mr. W. Ransom for elocution; Mr. Burgess for drawing; and Mr. Banks for arithmetic. Twenty-seven volumes have been added to the library, at a cost of £5 19s. 4d., and 3,249 volumes have circulated during the year. During the year 139 numbers joined and 96 left. The present number is 398, the average number of members during the last five years being 339. The committee have again, during the past year, united with the sister Institution at St. Leonards in carrying out a regatta fête. The lecture session was also opened with joint soirées; the first half-course being opened with a soirée in the Music Hall, Hastings; the second half-course with a soirée at the Assembly Room, St. Leonards. A plan was adopted whereby any student from the classes at St. Leonards should be examined at the class examinations, but none presented themselves from that Institution. The two Societies have again held a preliminary meeting, and have decided to hold a fête on the next regatta day. The committee "regret that the members continue to evince so much apathy as regards the examinations of the Society of Arts." They would gladly receive any hints from the members which would point out a mode of bringing about a more satisfactory state of matters. The Committee, in conclusion, congratulate the members on the continued success of the Society. "They might have initiated changes that would have made the Society more attractive to the thoughtless and the gay; but such a course would not have been so conducive to the real welfare of those who are and ought to be benefited by the operations of a Society of this sort." "The object of such an institution as this" (say the Committee), "should be the spread of education. To help the self-educating is the honourable aim of the institution." The balance-sheet shows that the receipts have been £238 1s. 2d.; that the expenditure has been £171 15s. 3d.; that there is a balance in hand of £66 5s. 11d.; and that the liabilities are nil.

PARIS EXHIBITION.

The beautiful weather which has prevailed since April has produced an extraordinary change in the Champ de Mars; the trees, shrubs, and grass are beginning to create something like harmony in the heterogeneous composition of the park, and the horticultural garden is rapidly developing its beauties; in another fortnight both (but especially the latter) will be delightful. The remaining unarranged portions of the Exhibition, within doors and without, are being got into order, some of them rather too gradually, and the amount and variety of the objects exposed are positively embarrassing.

Amongst the important additions made to the collection within doors during the last fortnight is that of the History of Labour, or Retrospective Museum, and although not complete it contains a most magnificent collection. The French portion is, of course, infinitely larger than that of any other country, and is admirably arranged; and there is this great advantage as regards the whole gallery—there is ample room between the cases, and the light is excellent. The French Commission is enabled to illustrate each epoch, from the age of bone and flint to the eighteenth century, very completely, and it is the first time that a great systematic exhibition of the kind has taken place; former retrospective collections have been crowded with beautiful or extraordinary productions, but this one represents very fairly the rise, progress, decline, *renaissance*, and many of the accidents in the history of handywork, and is thus an admirable school for the student in art-manufacture, while it indicates in a curious manner the tendencies and characteristics of the various ages.

Recent discoveries and discussions have given a special interest to the illustrations of the early ages of civilization; and the collection of bone, flint, and bronze arms and implements is remarkably fine. This applies not only to the French, but to every other department. Switzerland, for instance, contributes a choice collection from the lake-dwellings, with other antiquities of the kind.

There is, as yet, no catalogue of any division but that of England; the Danish catalogue as well as the Russian are nearly, if not quite, ready, but the French will take some weeks yet to prepare. Fortunately, the absence of catalogues is not a serious matter; special articles are generally labelled, and the great series tell their own tale.

The French department will be tolerably rich in all the grand divisions of decorative manufacture; the title, history of labour, is a misnomer; it should have been history of decorative art, for, with the exception of Prussia, there is no attempt to illustrate the history of any of the usual arts; in the early epochs there will be found some very curious specimens of pottery casts and bronze figures; the collection of enamels is remarkably fine, so is that of faïences; and that of china will be so when the two last rooms are arranged, which will only occupy a few days; the goldsmiths' art is fully represented in every epoch, and forms, altogether, a magnificent collection; this, of all other classes and other objects in the collection, presents the longest historical series. Denmark, Sweden, and Norway have highly interesting collections of a totally different type, and presenting more novelty to the great majority of visitors; old arms, breech-loaders, of the 15th and 16th centuries, and a small rifled cannon will attract great attention; Slavonic art is generally well illustrated.

Holland and Belgium, Spain, Portugal, and Italy, have not yet opened their doors to the public, but the last-named will present a very beautiful collection of bronzes and terra-cotta, amongst other items.

Prussia exhibits no decorative art, but a most complete series of ploughs, from the earliest forms to those of the present day, by Dr. L. Rau. The models number nearly two hundred, and are perfectly executed.

The Russian court contains a highly-interesting col-

lection, admirably arranged. It consists principally of old bronze work, jewellery, ancient arms and armour, curious plate, and some reproductions in plaster of the curious wood and stone carving of the Cathedral of St. Demetrius, and the churches of Saint John and Saint Isidore, at Rostov.

The British division completes the series worthily; it includes a small but choice collection of Celtic and Saxon ornaments, croziers, &c.; a series of caques of the most curious antique forms, with a few fine bits of work; some magnificent chased, engraved, and jewelled silver, and gilt work, including two silver tables; immense silver looking-glass frames, and some other specimens of plate sent by Her Majesty; some beautiful enamelled and chased work of the 14th and 15th centuries; English and Irish, and some fine examples of later times; some good specimens of Wedgwood, Chelsea, Derby, and Worcester ware, and other rare pieces of light-coloured Fulham stone ware. There is also a most curious collection of lace, selected from the collections of Mrs. Ellis, the stone and the Nottingham School of Art, ranging from 1589 to 1800, and filling fourteen frames; and a very remarkable set of specimens of calico printing, from 1760 to 1790, by the firm of Messrs. W. Bell and Co., who were succeeded in their business by Messrs. Liddiard, and are now represented by Messrs. W. G. Cooper and Co.

Some manuscripts and other articles from the British Museum will complete the collection, which has been got together and arranged by Mr. George Wallis, to whom it reflects great credit.

There is also a supplementary collection, which has already attracted the attention of all the foreign architects and artists, namely, a collection of photographs of a few actual specimens of the marvellous architecture and ornamentation so little known to Englishmen; as a French artist expressed, a complete revelation to nearly all the rest of Europe. This collection has been arranged by Mr. James Fergusson, and forms an admirable pendant to the British gallery.

The picture galleries may now be said to be complete, with the exception of the placing the names and numbers on the frames, which is now being carried out; the novelties there observed are eight frames containing some very curious specimens of Chinese art.

Additional interest has been given to the collection of pictures and drawings by the publication of the report of the jury, which has been even more painstaking than the Commission, the whole number of pictures awarded being but fifty-nine, or eight less than the number placed at its disposal.

Four of the grand prizes have been awarded to French artists: Meissonnier, Cabanel, Gérôme, and Théodore Rousseau; the four others to Ley, of Belgium; Kaulbach and Knaus, of Prussia; and two to Italy. First-class medals are given to Breton, Fromentin, Millet, Robert-Fleury, Brida, Daubigny, of France; to A. Stevens and Willem, of Belgium; Calderon, of England; Rosales, of Spain; Matejko, of Austria; Hirschelt and Piloty, of Bavaria. Second-class medals to Hébert, Corot, Jalabert, Dupré, Brion, Gidé, Vauthier, Yvon, Hamon, Delaunay, and Rosa Bonheur, of France; Nieuwenhuis, of England; Menzel, of Prussia; Sigismund, of Austria; and Claes, of Belgium. Third-class medals to Belly, Brissot, Charles Comte, Veffier, Baron, Bugeureau, Levy, Cabals, de Curzon, and Puvion de Lavannes, of France; Adam, of Bavaria; Orchardson, of England; Gisbert, of Spain; Achenbach, of Prussia; Israels, of Holland; Wurzeneger, of Austria; Farinacci, of Italy; Gonzalvo, of Spain; and the only prize for water-colour drawing, to Walker, of England.

The horticultural competitions are going on regularly, and Messrs. Veitch and Son, of Chelsea-lane, won the first prize for a lot of fifty species and varieties of rare plants grown in the open air, and another first prize for new plants disseminated.

The industrial juries have almost finished their examination, so that, with the exception of competitive trials in the classes of agriculture and horticulture, which will be spread over the whole period, the awards will all be made by the end of June.

The number of visitors is now very large, and the Exhibition has become the event of the day.

The following letter, addressed by Mr. Owen Jones, to the editor of the *Times*, will be found useful to all who visit the Exhibition:—

At the Exhibition of the Works of Industry of All Nations in 1861, the artistic world was startled by the revelation of the vast amount of elegance of design and propriety in its application exhibited in the works of the Oriental exhibiting countries. This impression was strengthened in the Exhibitions of 1855 and 1862, and in many directions the influence which Oriental art had exercised during the period which had elapsed since 1851 was recognised.

In the present Universal Exhibition of 1867 we still find India, Tunis, Egypt, and Turkey taking the highest rank in the application of art to manufactures. The shawls, carpets, mats, metal-work, and painted boxes of India; the embroidery of Tunis, and carpets of the Ottoman Empire, all exhibit the same unvarying principles of design, elegance, and refinement for which we sometimes look in vain in the art productions of European countries. By an unerring instinct and tradition they are able to apply ornament to the surfaces of objects they desire to decorate in the exact proportion and scale which the general form, material, and destination of such objects require. In the balance of colours, and in the distribution of lines of the ornament, they arrive at a perfection which it seems beyond the European mind to reach. To be fully satisfied of this it would be sufficient to compare the distribution of ornament on an Indian lacquer box of the humblest pretensions with the highest class enamelled works designed on Oriental principles exhibited by houses of justly European celebrity.

In the attempt which the French have made in the present exhibition to decorate some of the courts which contain the Oriental treasures in their own style we see how little the principles of decoration and ornamentation which the exhibited objects themselves display have been understood or appreciated by those who undertook the task. Ornaments have been misapplied in every direction, magnified from original sources out of all proportion, and mixed up with others of pure invention.

It would be a painful and invidious task to criticise in detail the decoration of these courts. To have rendered them worthy of the objects they enclose would have required years of preparatory study, and an amount of care and skill in the execution far beyond that which was at command, and which, perhaps, the temporary purpose which these decorations had to fill would hardly justify. I cannot therefore but regret that the attempt should have been made, feeling that it has cast an unmerited air of vulgarity over an art which is in reality so refined, and indisposed the casual observer to look within for that refinement and beauty which it overlays.

I am here led to the consideration of how far it is in any case desirable, in a building intended for such varied contents as an international collection, to attempt any decoration beyond that which the building itself may require; it is certainly not desirable to construct decoration.

In the building of 1851 there was, properly speaking, no decoration; beyond the colouring of the various constructive features of the building the objects exhibited were left to form the chief attraction, and themselves made up the decoration. In 1855 a little more was attempted; in 1862 too much, perhaps, of ornamentation, which in so vast a structure added little to the general

effect that might not have been supplied as well or better by more simple means—in fact, the machinery annexe was an example of what might have been done with the main building in this direction.

The present building, from its peculiar plan and construction, may, for all practical purposes of effect, be said to have disappeared, as, with the exception of the grand avenue and the machine gallery, it nowhere enters into composition with the articles exhibited. It is not likely that the plan of this building would be followed in any future exhibition in England. The circular form evidently entails too many sacrifices of convenience and effect. But the same system does appear to have many advantages, and we can conceive it carried out with parallel lines round a central hall with good results. In this central hall might be placed objects on which the various exhibitors might wish to stake their reputation and chance of reward, and which should have first passed a jury of selection. The present collection is too much like long lines of shops. Beside the many articles worthy of study there are far too many that a walk on the Boulevards would equally well bring to notice. Of course, exhibitors are desirous of showing examples of every variety of their manufacture; but international exhibitions should not be allowed to drift into mere commercial displays. They were intended to record the industrial progress of nations at various intervals of time, and objects which in no way exhibit this progress should be excluded, or, if that could not be done, they would, at least, find no admittance in our hall of honour.

We would venture to recommend the visitor who desires to study this exhibition with reference to the influence of art on manufactures, to commence his studies with the Oriental collections. When thoroughly impressed with the true principles of decoration and ornament, which he will find in these works, and carrying these principles in his mind during his visits to the collections of European countries, we feel assured that he will value these latter only so far as they observe the general laws of all art, which Orientals so instinctively follow—laws which were equally followed in all great periods of art, and which are to be found in all great works of the past. It is the neglect of these unvarying principles which leads so often to ugliness and bad taste in the incessant search of the present time after novelty, irrespective of fitness.

Doubtless the visitor will find throughout the international collection many objects to be admired, and many attempts to struggle against the fashion of the hour; but there are still by far too many violations of true art, too many instances of forms built up one on the other, without due regard to the proper transition from one form to the other; too many instances of impure form and discordant colouring; and we believe the visitor will return again and again to examine the lovely productions of the Indian looms, the delicate refined ornamentation of their metal and lacquer work. No object, however humble, appears to escape art influence. They seek not after novelty, yet every object is a new delight, as we feel how every touch of the pencil or the graver is directed by a mental action. Not a line is drawn that could be better placed in any other direction. Such as the mass is, so are the details. Not so with European works; they may more or less satisfy us, but there is always something to offend, and which we would desire to see otherwise than as we find it.

Fine Arts.

ADDITIONS TO THE LOUVRE.—Some recent acquisitions have been added to the galleries of the Louvre, including the "Birth of the Virgin Mary," by Murillo, and the "Sainte Appoline" of Zurbaran; three small works by Chardin; the portrait of Denon, the first keeper of the Louvre, by Prudhon; and a portrait of a woman by Madame Haudebourg Lescot.

A CENTENARIAN ARTIST.—There are two pictures at present to be seen in the Salon, in Paris, painted by M. Jean F. M. de Waldeck, born at Vienna, in Austria, on the 16th March, 1766, and who was pupil of Vien, of David, and of Prudhon. These works were, according to the declaration of the artist, completed at the end of last year only.

Commerce.

TEA CULTIVATION IN INDIA.—It appears that there seems to be at last some likelihood of a settlement of this vexed question. A memorial from the tea planting interest in Eastern Bengal has been laid before the Government of India, and from the cordial reception accorded to the deputation, which was remarkably influential, representing eighty firms, thirteen companies, and six banks, the importance of the subject, and the magnitude of the interests involved in it, seem to be acknowledged by the officials. In urging their claims, not for any Government protection, but simply for permission to manage their affairs in the way most likely to be conducive to their own interests, the deputation refrained from imputing any blame to the Government, attributing their losses wholly to "mercantile speculation, bad management, and a malarious climate." As the same reasons for this reserve do not exist on the part of the public, inasmuch as they have no officials to conciliate, we (*Produce Markets Review*) need not hesitate to speak with more plainness on the subject, and to lay a considerable portion of the blame on the Indian Executive. If it be not in the power of Governments to aid the development of commerce, at least they should abstain from placing unnecessary obstacles in its path, and amongst these impediments the one-sided legislation on behalf of the coolies must undoubtedly be classed. Granted that the only object that the Government had in view was the protection of the inferior and weaker classes against the possible tyrannical exactions of the planters, still there were many other ways of effecting this desirable object without necessarily entailing ruinous losses on the planters at the same time. The most effectual means for facilitating communication between the coolies and the employers of labour would have been, as the memorialists point out, the formation of proper roads between Bengal and Assam or Cachar; as in that case all the expenses, risks, and diseases incidental to long voyages by steamer would have been obviated. "Tea coolies have to be recruited," we are informed, "kept in dépôts in Calcutta or Kooztea, conveyed in steamers to their destination, and exposed to the chance of neglect and the certainty of sickness, in a malarious climate, far away, in many cases, from public opinion, just as in the case of the colonies. It is true that self-interest in most cases, and high principle in a few, lead the tea-planter to care for a labourer whose importation alone has cost him £8 or £10, and without whom his garden would relapse into jungle. But certain as is the good treatment of the coolies on the whole, there have been cases of the opposite, and the interests of ill-paid and not always highly-cultivated assistant-planters in isolated gardens are not those of their employers, or at least so strong as to check occasional outbursts of temper. Government interference then is necessary, but only so long as emigration has to be carried on in crowds and river-steamers. The moment a road is made from Bengal to Assam, it is evident that coolies will find their way there just as they do to other districts. It is the old story of a want of communication, to which the Orissa famine, in its intensity and long continuance, may be traced no less than the Assam collapse." With a liberal disbursement of funds by the Indian Government for the formation of roads, all the evils alluded to above, and the necessity of any official interference

with the labour question, would at once be done away with.

CULTIVATION OF HOPS.—Professor John Wilson, in his report on the agricultural exhibition held at Vienna last year, mentions that, along with the samples of Hungarian hops was shown a plan of the method of cultivation carried out at Bellen, adapted for all our districts where wood suitable for hop-poles is scarce. Wooden pegs or short stakes are driven into the ground, at such distances apart as it is intended to plant the vines; and at longer distances—usually about 50 to 55 yards—light poles are erected, with a height of from 12 to 15 feet above the surface, so that there are parallel lines all over the ground of short stakes or pegs placed at certain distances, and projecting about 8 to 12 inches in height, while parallel rows of poles, from 11 to 15 feet high, cross these at right angles, and at from 20 to 25 yards' distance apart. A stout wire is stretched horizontally from pole to pole all over the ground, while vertical wires or light rope, made of any suitable material, are attached to the pegs and carried up and fastened to the horizontal wires, thus offering a steady support to the hop vine during the period of growth. At harvest time the ropes are detached and carried to the picking stage with the vines, and the field cleared for the usual tillage operations without the trouble or expense of shifting, stacking, and resetting the poles. This plan has been carried out during several seasons at Bellen, and has been introduced into Wurtemberg, Baden, Bavaria, and other hop-producing countries, with satisfactory results.

Colonies.

ENGLISH CAPITAL IN AUSTRALIA.—From several sources of information it appears that English capital is finding an outlet in pastoral investments in Australia. Paragraphs have appeared in local journals announcing the transfer to British proprietaries of large squatting stations. This development has disclosed itself in Queensland, but to a much larger extent in Riverina. The movement is very desirable, and deserves every encouragement that can be given to it. An extensive transfer of stations to new and wealthy owners would be most beneficial. It would directly benefit local owners struggling with heavy liabilities; it would be advantageous to mortgagees, especially banking mortgagees, with advances locked up for indefinite periods by bringing their capital once more within their reach and control; and finally (says a colonial journal), it would probably be a highly profitable mode of investment for the new purchasers if possessed of resources for properly and efficiently working these great properties. There are such solid profits to be made out of sheep and cattle stations, by persons with sufficient independent means, that once the introduction of English capital was set in motion its influx would be constant and regular. The sinking of wells and the formation of reservoirs would immensely increase the capability of the arid country now useless in the Riverina district, and this is the preliminary outlay which many of the present station occupiers cannot afford. The loan and mortgage companies have done something in giving accommodation, but rich ownership would benefit the district more than the limited aid these corporations can give. The banks have lent millions of capital, drawn from Victorian depositors, upon the security of stations in Riverina. They should, by firmly applied pressure, compel squatting borrowers to throw themselves into the arms of a good class of purchasers.

COMMERCE BETWEEN INDIA AND AUSTRALIA.—An article in the *Madras Times* comments on some samples of wine lately shipped from Victoria by the Murray Valley Vineyard Company, and recognizes great improvement in their ripeness and quality, as compared with those for-

warded the previous year. It expresses an opinion that frequent drinkers of these unadulterated wines would prefer them to those of European vintages, adulterated to suit the English taste. It concludes by looking on to a not far distant time when India and Australia may be more closely connected by commerce than at present, and when the produce of Australian farms, runs, and vineyards will be exchanged for coffee, sugar, and other Indian productions.

Notes.

SCIENTIFIC SOCIETIES IN RUSSIA.—A Society of History was formed at the end of last year, in Saint Petersburg, with the view to the publication of materials relative to the history of Russia from the time of Peter the Great. The first meeting of the society took place on the 12th March, in the house of the Prince Gortchakoff, under the presidency of the hereditary Grand Duke; several important public documents were communicated to the meeting. The Geographical Society of Russia has been authorized to establish a section in the north-west, the seat of which will be Wilna; the chief object of this new section is to study the province in an archaeological, statistical, and ethnographical sense. An ethnographical exhibition has been announced to take place at Moscow during holy week; the idea of thus collecting the illustrations of Slave ethnography has been very warmly taken up by the *savants* not only of Russia but of the adjoining populations speaking a Slave idiom; and it is said that the collection of drawings, photographs, arms, utensils, and other articles and illustrations, is extremely curious. Great arrangements were announced to have been made for the visitors expected from Austria and Turkey, who were to be lodged in thirty apartments prepared for them in the Hôtel Kochoreff.

MEDICAL CONGRESS IN PARIS.—A scientific medical congress is announced to open in Paris on the 16th of August, under ministerial patronage, to which all the medical world is invited. A committee, including Dr. Wurtz, dean of the Faculty of Medicine, Drs. Tardieu, Bouilland, and many more eminent physicians and surgeons, is appointed to organise the congress. The secretary, to whom all communications are to be addressed, is Dr. Jaccoud, of 4, Rue Drouot, Paris.

MONT CENIS TUNNEL.—According to the official report received by the Minister of Public Works at Florence, it appears that the boring works of the great tunnel of the Alps at Mont Cenis, on the north side of Modane, had passed, on the 8th of last March, the bed of quartz which had been met with in June, 1865, and they had passed through a schistose limestone, mixed, and were now in pure limestone. The length of quartz passed was 381 metres, approaching in a surprising degree to the 348 metres, estimated at the beginning according to the external appearances and the inclination of the beds. From the 8th of March the nature of the rocks has been always the same, and the advancement in the small tunnel, which in the quartz bed never exceeded on the average 15 metres a month, has almost entirely resumed its original progress. It is satisfactory to publish the results obtained in the two fortnights of March, results which show that the work of boring has gone on with regular development on both sides. Progress during the first fortnight in March in the small tunnel was—south side, 34.65 metres; north side, 19.37 metres. During the second fortnight in March—south side, 41.25 metres; north side, 38.17 metres. Total work in the month, 133.34 metres. Total length of the bored part—south side, 4,119 metres; north side, 2,628.25 metres; total, 6,647.25 metres. Total length of tunnel, 12,220 metres. Portions bored, 6,647.25 metres; remaining to bore, 5,672.65 metres.

INTERNATIONAL MONEY ORDERS.—In October, 1864,

a convention was concluded between the French and Italian governments for the reciprocal transmission of money orders through the post offices of the two countries for the payment of articles bought in France and Italy by private persons. A statement of the amount of orders sent by the French Post-office to Italy and by the Italian Post-office to France, and paid, from the 1st of October, 1864, to the 31st of December, 1866, shows that in October, 1864, the month in which the convention was concluded, there were 933 orders, amounting in all to about 53,000 francs, sent through the French Post-office to Italy. In December of last year this had increased to 3,519 orders, amounting to more than 180,000 francs. The orders sent from Italy to France were in October, 1864, 920, amounting to 69,000 francs, and in December last, 2,395, amounting to about 194,000 francs. "There can be no doubt," says the Paris correspondent of the *Times*, "that a similar arrangement between France and England would be mutually advantageous, and there is no comparison between the quantity of articles bought by Frenchmen in England and *vice versa*, and those between France and Italy. For the convenience of both post-offices it might be stipulated that 200 francs, or £8, should be the *maximum* of the money order. I am assured that the French Postmaster-General declares himself ready and willing to sign such a convention, but some of the officials of the English Post-office are opposed to it—why, I cannot say."

THE EMPRESS EUGENIE is preparing two collections of pictures and other objects connected with the Empress Josephine and Marie Antoinette. When completed they are to be open to the public during the Exhibition, at the palaces of Malmaison and the Petit Trianon.

MEETINGS FOR THE ENSUING WEEK.

- MON.**.....Society of Arts, 8. Cantor Lecture. Mr. Chaffers, "On Pottery and Porcelain."
R. United Service Inst., 84. Capt. T. E. Symonds, R.N., "The Combined End-on and Broadside System."
R. Geographical, 84. 1. Capt. Sherard Osborn, R.N., "On Chinese Tartary." 2. Mr. A. G. Findlay, "On Dr. Livingstone's Last Journey, and the Sources of the Nile."
Society of Engineers, 74. Discussion on Mr. Vaughan Pender's paper, "On Water Tube Boilers."
- TUES.**...R. Medical and Chirurgical, 84
Civil Engineers, 8. 1. Discussion upon Mr. Chance's paper, "On Optical Apparatus used in Lighthouses." 2. Mr. Edward Byrne, "Experiments on the Removal of Organic and Inorganic Substances in Water."
Photographic, 8.
Anthropological, 8.
Royal Inst., 3. Dr. Miller, "On Spectrum Analysis."
- WED.**...Society of Arts, 8. Mr. W. Fothergill Cooke, "On New Machinery for Cutting, Tunneling, Quarrying, and Facing Slate, Stone, and Marbles."
Pharmaceutical, 11. Annual Meeting.
- THURS.**...Zoological, 4.
Chemical, 8.
Syro-Egyptian, 74. Mr. D. W. Nash, "On the Mutual Influence of Assyrian and Egyptian Civilisation."
Royal, 84.

Journal of the Society of Arts.

FRIDAY, MAY 17, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

MAY 22.—Derby-day. *No meeting.*

MAY 29.—“On the Water Supply of the Metropolis in relation to the Conservancy of the Thames and its tributaries, and the demands of the Water Companies.” By J. BAILEY DENTON, Esq.

CANTOR LECTURES.

The concluding lecture of Mr. CHAFFERS' course, “On Pottery and Porcelain,” will be delivered as follows:—

LECTURE VII.—MONDAY, MAY 20TH.

ENGLISH PORCELAIN.—Bow—Chelsea—Derby—Worcester—Liverpool—Wales—Plymouth—Bristol—Lowestoft—and other Manufactories—Battersea Enamel, &c.

The lecture commences at eight o'clock, and is open to members, each of whom has the privilege of introducing one friend.

CONVERSAZIONE.

The Council have arranged for a Conversazione on Thursday evening, the 23rd May, at the South Kensington Museum, cards for which have been issued.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object. The following gentlemen constitute the Committee:—

Rt. Hon. C. B. Adderley, M.P.
C. W. Aitken.
Edward Akroyd, M.P., *Vice-Pres.*
Sir Wm. G. Armstrong, C.B.
A. S. Ayrton, M.P.
S. A. Beaumont.
John Bell, *Memb. of Council.*
Professor Bentley, *Memb. of Council.*
Lord Berners, *Vice-Pres.*
Hon. and Rev. S. Best.
D. Robertson Blaine, *Memb. of Council.*
W. H. Bodkin (Assistant-Judge), *Vice-Pres.*

Sir J. P. Boileau, Bart., *Vice-Pres.*
R. K. Bowley.
Antonio Brady.
Rt. Hon. H. A. Bruce, M.P.
Decimus Burton.
C. Buxton, M.P.
The Earl of Caithness, *Vice-Pres.*
Lord Eustace Cecil, M.P.
R. L. Chance.
Harry Chester, *Vice-Pres.*
The Masters of the City Companies.
Henry Cole, C.B., *Vice-Pres.*
Robt. Coningsby.

Rt. Hon. W. Cowper, M.P.
Sir Francis Crossley, Bart., M.P.
J. Bailey Denton, *Memb. of Council.*
Lord de l'Isle and Dudley, *Vice-Pres.*
The Duke of Devonshire.
Charles Dickens.
James Easton, *Memb. of Council.*
C. W. Eborall.
Lord Ebury.
Lord Elcho, M.P.
William Fairbairn, F.R.S.
Professor Fawcett, M.P.
Peter Graham, *Memb. of Council.*
The Earl Granville, K.G., F.R.S., *Vice-Pres.*
The Earl Grosvenor.
Mr. Hansard.
G. W. Hastings.
Wm. Hawes, F.G.S., *Vice-Pres.*
J. Pope Hennessy.
Sir Rowland Hill, K.C.B.
Chandos Wren Hoskyns, *Vice-Pres.*
T. Hughes, M.P.
Blanchard Jerrold.
Rev. C. Kingsley.
Hon. A. F. Kinnaird, M.P.
Lord Henry G. Lennox, M.P., *Vice-Pres.*
The Bishop of London.
The Sheriffs of London and Middlesex.
Rt. Hon. Robt. Lowe, M.P.
Lord Lyttelton, *Vice-Pres.*
Archbishop Manning.
Henry Maudslay, *Memb. of Council.*

Rev. F. D. Maurice.
The Lord Mayor.
J. Stuart Mill, M.P.
Rev. Dr. Miller.
The Bishop of Oxford.
J. Slaney Pakington, *Memb. of Council.*
Right Hon. Sir John S. Pakington, Bart., M.P., *Vice-Pres.*
Alderman Sir B. S. Phillips.
Sir Thomas Phillips, Q.C., F.G.S., *Vice-Pres., Chairman of the Council.*
The Duke of Richmond.
Rev. W. Rogers.
The Marquis of Salisbury, K.G., *Vice-Pres.*
Titus Salt.
Sir Francis Sandford, *Vice-Pres.*
Colonel Scott, R.E., *Memb. of Council.*
The Earl of Shaftesbury.
Benjamin Shaw, *Memb. of Council.*
Sir J. P. Kay Shuttleworth, Bart., *Vice-Pres.*
S. Smiles.
Seymour Teulon, *Treasurer.*
Thomas Twining, *Vice-Pres.*
Alderman Waterlow, *Memb. of Council.*
E. W. Watkin, M.P.
G. Watts.
George F. Wilson, F.R.S., *Memb. of Council.*
Vice-Chancellor Sir Wm. Page Wood, F.R.S., *Vice-Pres.*

The Council, on the recommendation of the Committee, have passed the following minute:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government, to facilitate the visits of skilled artizans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed, in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the

men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

HARVESTING OF CORN IN WET WEATHER.

The Council of the Society of Arts have resolved to offer the Gold Medal of the Society, and a Prize of Fifty Guineas, for the best Essay on the Harvesting of Corn in Wet Seasons.

The first part of such essay—after noticing the various systems at present adopted in damp climates for counteracting the effects of moisture upon cut corn in the field, and for avoiding such exposure in wet seasons by peculiar harvesting processes—should furnish a practical and analytic exposition of the best available means:—

- 1st. Whereby cut corn may be protected from rain in the field.
- 2nd. Whereby standing corn may, in wet seasons, be cut and carried, for drying by artificial process.
- 3rd. Whereby corn so harvested may be dried by means of ventilation, hot air, or other methods; with suggestions for the storage both in the ear and after threshing.
- 4th. Whereby corn, sprouted, or otherwise injured, by wet, may be best treated for grinding or feeding purposes.

The whole to be supplemented by a statement of practical results, and actual cost of each system described; and authenticated estimates of any process proposed for adoption, based upon existing but incomplete experiments.

The above requisitions are given suggestively; not to bind the writer to the order or to limit the treatment of the subject, provided it be kept within the scope of practical experience and utility.

The essays must be sent in to the Secretary of the Society of Arts on or before the 1st of January, 1868.

The Council reserve the power to withhold the whole or part of the prize, in the event of no essay being, in the opinion of the judges, of sufficient merit.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

A meeting of the Sub-Committee on Meat was held on Wednesday, April 17th, at which there were present Mr. Benjamin Shaw (in the chair), Mr. J. Ware, Mr. Harry Chester, Professor J. Wilson, Mr. Ludford White, and Mr. E. Wilson.

Mr. HENRY GRAINGER, having attended upon the invitation of the Committee, stated he had been for many years engaged in the foreign provision trade in London and in Liverpool, and was three years since President of the Liverpool Chamber of Commerce.

The CHAIRMAN explained to Mr. Grainger that the object of the Committee was to inquire how, and from what sources, the supplies of nutritious food for the labouring classes in this country could be increased and cheapened; and Dr. Edward Smith, having, in his book "Practical Dietary," mentioned bacon, and particularly American bacon, as a valuable article of food, the Committee would be glad to hear whether, in Mr. Grainger's opinion, the importation of that commodity could be increased, and whether it could be made a good and useful article of food at a low rate?

Mr. GRAINGER replied that the quantity could be increased indefinitely; but it was a question of price. As far as his own experience went—and that had been very extensive—he had never been able to get from any part of the world salt beef which the English people would eat at a low price. During the late American war he said, when the Southern markets were closed, very large quantities of American bacon were exported to this country, at a first cost of threepence per pound. Since the close of the war the price had advanced considerably, the first cost wholesale being, in round figures, fivepence per pound by the hundredweight or ton. The quality of the bacon sometimes varies, but is tolerably uniform. The present price of American bacon was from 4s. to 5s. per cwt., according to the quality of the meat; the retail price would be from 6d. to 7d. per pound. English or Irish bacon was from 2d. to 3d. per pound dressed. American bacon is never considered to be of so good a quality for consumption in this country as English or Irish cured. One reason is, the Irish bacon, from the rapid means of conveyance, can be more mildly cured, whereas the American bacon, having to come a considerable distance, requires a stronger cure, and is very salt. The English people like things mild, and will not eat very salt meat of any kind. The Irish cured bacon is more adapted for our consumption, and the best qualities form an article of luxury on the breakfast-table. As far as he was aware, no attempt had been made to send meat from America without salt; he did not think it would answer, owing to the extreme fastidiousness of the people in respect of food. Although the very finest quality of salt beef was offered in establishments in various parts of the country at 3d. per pound it was a total failure; the miners and colliers would not eat it; that was meat which came from the United States, and of the prime quality, but highly salted, which prevented its sale. The salting went beyond the ordinary salting of meat in this country, but not beyond that which was supplied for cabin provisions of first-class ships. He believed the present supply of American beef in this country was not large, and such as was on hand was rather dear; the price of ship's beef varying from 4½d. to 6d. per pound, bought as ship's stores. Some of the meat was without bone; but, strange to say, preference was given to meat with bone for ship's use. He would be happy to send a piece of this description of beef for the inspection of the Committee, and it would be found to be of a quality of meat

equal to anything that could be obtained in Leaden-hall-market, and not more salt than the Committee would like for their own eating. In troop and emigrant ships they would find beef of very fine quality. He had seen specimens of the Australian cooked beef, which had lately been imported into this country, in cases hermetically sealed, but he very much doubted whether it would ever acquire a large consumption by the people here. Salted meat in the raw state from Australia and South America, was at one time sent over in large quantities, but it was a perfect drug in the market. Such provisions were very rarely purchased by the public. At the principal places of preparation of such meat—beef and pork—as he (Mr. Grainger) had spoken of, it would pay the people to produce the raw article in the Western States of America to sell it at 2d. per lb., but of late years they have obtained a higher price than that both for beef and pork; but it could be produced there at 2d. per pound. A half-penny per pound would cover the expense of carriage from the Western States to the seaboard, while the cost of the sea passage and charges would be equal to another half-penny per pound. The quantity of bacon was larger last year than in the previous one, though it was nothing like the maximum during the American war. He believed the quantity could be increased indefinitely if there were the means of paying for it. For his own part, he decidedly preferred, for his own eating, pork fed in England or Ireland, from the fact that the American pork was, to a large extent, fed upon Indian corn, which made a rich meat, with a great tendency, from its richness, to turn rancid, when prepared as bacon. The over-greasiness of the American bacon was one objection to its use in this country; the want of firmness in the meat he attributed in a great measure to the way in which the hogs were fed. After “priming” in the woods, they were turned into the maize-fields, where they got a second feeding, and the result was one portion of the fat was hard and the other soft. With the corn-fed hogs, the whole of the fat would be firm, and a proper firmness of the meat was a test of its quality. The fat should be firm to the touch and the lean tender.

The CHAIRMAN asked Mr. Grainger whether he looked to future large importations of either meats?

Mr. GRAINGER replied there were very large cattle raisers, and large quantities of salt meat were now shipped to this country. The great centres of the trade were Cincinnati and Chicago, the latter having taken the lead. About three-fourths of the exports were consigned to Liverpool, and one-fourth to London, but a great deal was sent by railway from Liverpool to London, so that the relative consumption of the two districts could not be estimated on that account. He thought the amount of curing that was sufficient to preserve English and Irish bacon would be sufficient to preserve the American bacon during the short time that was necessary for its transit from the Western States to this country, but not for keeping during the time it had to be held for distribution in this country. The curing for two or three months produced the supply for twelve months, and mild cured bacon would not keep good for that time. The Irish bacon was not thoroughly cured, but thoroughly cured bacon would keep for any length of time without becoming tainted. Large quantities of pork were sent from America, as barrelled pork, in wet pickle, which was very good indeed, and met with a ready sale. He saw some of this description of pork the day before, the price of which wholesale was 5d. per pound. It was frequently sold by the retailers. It was not so salt generally as the American bacon; only moderately salt. There were other large markets for American meat besides our own; and very low prices in this country would be prohibitory to its importation, whilst better prices could be obtained elsewhere. If we were willing to give good prices there is no limit to the quantity they could send. Large quantities of bacon are imported from the north of Europe, from Denmark,

Holstein, and Hamburg, which in quality compares favourably with English and Irish, and the difference in price is only about a half-penny per pound. The price was the great criterion of quality.

The CHAIRMAN asked Mr. Grainger whether he agreed with the following passage in Dr. Smith's book on “Practical Dietary,” with regard to American bacon:—“The economy of bacon depends upon the price which is given for it. Thus, when 9d. per lb. is paid as a medium price for English or Irish dried bacon, the amount of nutriment which can be obtained for 1d. is only 530 grains of carbon and 11 grains of nitrogen; but American bacon, in a somewhat less dried state, is sold at 3d. and 4d. per lb., and at the latter price would offer 1,070 grains of carbon and 20 grains of nitrogen. The flavour of the latter is seldom so good as that of the former, since in the western parts of America the hog is chiefly fed upon acorns, hickory nuts, and other seeds called ‘mast,’ in the woods, and the curing is seldom so carefully performed as in this country; but when a fair sample of it is procured it is an agreeable food, and is far more economical than the English or the Irish bacon. From the imperfect feeding of the American pig, a large proportion of the fat runs out of the bacon when it is boiled, and the piece shrinks in size, so that the housewife cannot cut so many slices from a given weight; but if the liquor is made useful as food this is only an apparent and not a real disadvantage. There is at least five per cent more water in American than in well-cured English bacon.”

Mr. GRAINGER remarked that the method of feeding above described was formerly adopted, but had been to a great extent discontinued, as the people would not eat the acorn and mast-fed pork, and it was no longer imported into this country. If it were it would be unsaleable. To show the truth of Dr. Smith's observation, it is the fact that the Irish producers ship all their superior qualities of bacon to our markets, and import largely American bacon from Liverpool for home consumption. They did not mind its being a little greasy; what we regarded as the impurity of the article appeared to be a recommendation with them in the way they use it. They preferred giving 1d. per lb. less for American bacon, and shipping their own produce to England and getting a higher price for it. The Irish people are large consumers of American bacon. At the present time there was a better system both of feeding and curing pigs in America than formerly, and there was no fault to be found with either. Still, the American bacon was inferior to both English and Irish. The American pigs were more quickly fattened, and consequently became rancid by keeping. One would eat a portion of American bacon, and pronounce it good, but would not ask for more. There was no particular fault to be found with it in the eating, but it was not appetising.

Professor WILSON said during his visit to America he made it his business to inquire into the method of feeding and curing pigs in that country, and he found that the great bulk of the animals were fattened upon Indian corn. On the western prairies, where the soil would not grow wheat, Indian corn was cultivated in large tracts, and it was grown there to an extent that could hardly be conceived. He had seen maize crops from 12 to 14 feet in height. It was so for many miles. The farmers could not send it as corn to the market, and they turned hogs into these corn tracks by hundreds and thousands, and thus they carried the Indian corn to market in the shape of pork. That was what they called “condensing” it as pork. The hogs when fatted were sent to the large killing and curing establishments at Ohio, Indiana, and Terre Haute, to be made into bacon, and dried for home consumption. This pork was all of superior quality, being fed upon Indian corn. No better food could be given to the animals than the Indian corn, mixed with the juicy and sweet stems of the corn; but the pork was considered to be too rich for the

English palate. Pigs fed on potatoes and meal fatten slower; the fat is firmer, and the meat nicer eating. Some of the hogs were brought to as much as 200 lbs. weight. The factories were several stories in height. The pigs were driven up an inclined plane to the top floor. They were then placed together in rows, and then two men ran along on the backs of the pigs, with little pole-axes, and hit them on the head like playing musical-glasses. In this way they were taken to the top as live pigs, and, passing through successive stages, reached the bottom as cured pork, ready for drying as bacon. The system had altogether been brought to very great perfection.

Mr. GRAINGER observed, with regard to beef from South America and Australia, various attempts had been made to salt it and send it to our markets. The cattle were in the best condition for slaughtering, at a time of the year when the temperature of the climate was too high to admit of mild salting or pickling. If they deferred the salting till the winter time the meat would be in such a thin and lean condition that it would not be acceptable in this country, and thousands of packages have been sold here for less than the value of the casks. It might naturally be supposed that they could prepare that beef and send it over in great quantities; but owing to the climate, at the time the meat is in best condition, it could not be cured in the usual way. This remark applied equally to South American and to Australian beef. He had seen meat salted by the injection process of Dr. Morgan. That process had been partially successful; so much so that what was formerly sold at a guinea per tierce, from the peculiar state of the market, rose to 85s. per tierce, or about 3d. per pound. That was pickled in salt. Some of the beef and mutton sent from Australia had been sold here. The cooked canister beef prepared by Tindal's process he did not think would ever become of large or general consumption in this country by the lower classes. It would no doubt be used to a certain extent; as a little change from salt provisions it would be agreeable. He believed it had been found out that in these tins certain gases are generated, which produced dysentery when used to any large extent; and therefore it would not do to introduce it largely into the commissariat of an army. This remark, he believed, applied more or less to all meat preserved in tins. It was not, in fact, wholesome as a general article of diet. That was what he had heard. It might be used as an occasional change of diet, but should not be make a frequent article of food. The effects were seen in the provisioning of the troops in the Crimea. He believed there was a little selling now. All attempts of this kind had been failures, partly because when a tin was opened it required to be used immediately, and if kept it became spoilt. The Government were now preparing largely for themselves provisions for the navy, although it was done at an expense considerably above what the same class of provisions might be bought at, with the pick of the market.

Mr. LUDFORD WHITE said he could contradict from personal experience the statement that the preserved meat would not keep when the tin was opened. He had kept the meat good for a week in an ordinary larder.

Mr. GRAINGER believed, if it could be sold at the counter at 6d. per pound, there would be a demand for it. It was astonishing what a difference a penny per pound in bacon made in the consumption. American bacon, to meet with a sale in this country must be put on the counter at 6d. per pound. At the present time they could not dispose of any large quantity of American bacon at 7d. or 8d. per pound. If it could be sold retail at 6d. per pound he had no doubt four times the quantity would be sold. It made a difference of 300 per cent. in the consumption. It was easy for a person with technical knowledge to distinguish between cooked English and American bacon. He would not like the latter so well as the former. It was not prejudice, but there was that real difference which would lead to preference for the one

over the other. The best English and Irish bacon was at the present time 8d. per pound wholesale, and the retail price 10d. The only way to increase the consumption would be to increase the wages of the working classes, so that they might have the means of purchasing a fair proportion of the home as well as foreign produced meat. It was merely a question of price. If the price could be paid we might have meat from all parts of the world. In the words of the Americans, they could send us enough meat to sink our little island entirely. Probably as much meat might be sent from the banks of the Danube as from those of the Mississippi, but the cost of transit was a bar to the large exportation of it to this country.

Mr. CHESTER inquired whether any importations of pork were received from Spain?

Mr. GRAINGER replied it was rarely the case; there had been beef sent from Spain, but the price was high.

Mr. E. WILSON inquired whether any large supplies of beef had been received from Denmark?

Mr. GRAINGER replied very little direct. It was mostly sent to Hamburg, and thence to this country.

The CHAIRMAN asked whether the same difficulty with regard to climate, which had been mentioned, existed with regard to Buenos Ayres?

Mr. GRAINGER believed it did. A company was formed in Monte Video for the preparation of meat, with some promise of success. He apprehended that a modification of Morgan's process might answer. He had seen a great many tierces of it. There seemed a probability of making a perfectly cured article. The meat was by no means so salt as that termed "junk," and a good price was given for it. Up to the present time it was liable to suffer injury in crossing the line, and required to be put in proper order before it was used. He referred to Queensland. It was obvious the cattle would be in the best condition when there was most grass for them to eat. There were no stall-fattened cattle there, consequently they were fatter when there was abundance of grass, and that would be in the early part of the summer, when it was too hot for curing in the usual way.

Professor WILSON said but for the difficulties of transit no doubt we could obtain any amount of provisions from the Lower Danube. There was an attempt made at it last year. Two fat oxen were slaughtered at Vienna, and sent express to London. The meat arrived within 50 hours after it was killed, and a joint was soon after put down to the fire to roast. The price obtained was 64d. per lb. Seeing that meat was selling here at 10d. per lb. it was an inducement to try the experiment. If it answered they could send a hundred or two of fat cattle per week.

Mr. GRAINGER said the largest importation of American bacon was 500,000 boxes, of 400lbs. each. That was in the second year of the American War. Last year it amounted to only about 70,000 boxes. The quantity had been much less since the end of the American War. In reply to questions put by Mr. Wilson, with regard to the relative price of English and American cured hams Mr. Grainger stated that there was a more marked difference in the price of hams in favour of the former; American hams were for the most part unsaleable in this country. The legs sold better as wet pickled, but when they became hard, as hams, the people would not eat them. In fact it must still be borne in mind that the whole curing for the year must be done in two or three months, while the consumption extended over the whole year. He had remarked that the trade in American bacon began with a relish and ended with a nausea. He had seen fresh American hams almost as good as English.

Mr. CHESTER asked whether there was not a great increase in the importation of American cheese?

Mr. GRAINGER replied, the increase was very great indeed, and the prices had risen, in consequence of the improvement in the quality and in the manufacture that had lately taken place. The difference was only 2d. per lb. between the finest American and the finest

English cheese. The average quality was now very nearly equal to that of Cheddar. This was mainly due to the improved manipulation of the cheese, and Mr. Grainger explained that the plan had recently been adopted of establishing a cheese-factory for a whole district, instead of each person making his own cheese. The arrangements for the purpose were of the most perfect description, and by that means an uniform quality of cheese was obtained, instead of great variety of quality according to the individual methods of manufacture adopted. Each farmer delivered his quantity of milk at the factory every day, of which a record was kept. The factory was superintended by a man of practical knowledge and ability, and the result was American cheese had become, from its greatly improved quality, a very favourite article in this country. The demand for it was increasing, and the price had risen to nearly double what it was a few years ago. This system of manufacture had been adopted in most of the dairy districts of the American states. There were large factories of this kind in the State of New York and in Ohio. In a country where skilled labour was scarce, the mechanical appliances and methodical system of manufacture such as he had mentioned were evidently of the greatest advantage. The bulk of cheese was sold at the end of the season, and a *pro rata* division of the proceeds was made according to the quantity of milk sent in by each person. He believed the American cheese would have a very sensible effect upon the home manufacture, as the public would not select cheese below the quality of the best American. The American article had now established itself side by side with other articles in the provision markets of the country. Some of the cheese was made in English-shaped moulds; but American cheese was always distinguished by being wrapped in coarse canvas. Some cheese had been received from Sweden; that was not wrapped in cloth like the American, and he had sold some of it as high as 78s. per cwt., which was about 4s. above the price of American. It compared favourably with the best Cheddars. The importation of provisions from Canada was considerable, consisting of beef, pork, cheese, and a large quantity of butter. There were no climatic difficulties to contend against, as was the case in tropical latitudes. The resources of that country were rapidly developing. The head quarters of the export trade were Toronto, Hamilton, and Montreal. The transit had been the hindrance to larger exportations. Nothing was exported to this country from French Canada, and Newfoundland was a large importer of provisions from us and other countries. There was great hope from the development of the provision trade in Canada, as the articles were of a character which suited our markets. Self-interest, however, would lead them to produce an article that would suit our markets as nearly as possible, and there was every encouragement to improve the quality. They were quite aware of the necessity of salting as little as possible. Self-interest teaches people all these things. The love of making money is a greater stimulus than could be given by the action of this or any other committee; and looking to that they naturally made themselves acquainted with the best mode in which things are to be done; and it was not to be imagined that they were deficient in chemical as well as practical knowledge on these subjects.

The CHAIRMAN asked if there had been any attempt to preserve provisions from Canada otherwise than by salting?

Mr. GRAINGER was not aware of any; it would hardly say them, he thought, to do so. In the matter of fresh preserved provisions it was entirely a matter of confidence in the manufacturers; and in the provisioning of ships with such stores confidence in the article was of the greatest importance; and people preferred paying a higher price for that in which they had confidence rather than trusting to that which was cheaper. If a method of preserving provisions in a fresh state were dis-

covered, as compared with salted meat, it would be a question of relative price. The government used formerly to enter into contracts for the supply of meat for the navy, but latterly they had been induced to cure the meat for themselves. He thought this would, before long, be found to be a mistake; looking to the fact that a large quantity must be spoilt. The reason alleged for taking that course was that they could not depend upon the quality of the provisions supplied by the contractors, and they must take care that the soldiers and the sailors were well fed. He believed the present system involved double the cost, and that no better article was secured than would be the case under the contract system, under which the most rigid inspection was instituted.

Mr. WILSON asked whether, from Mr. Grainger's experience, there was a possibility of preserving meat for a long time without so charging it with salt as to cause it eventually to assume the character of "junk."

Mr. GRAINGER considered it must necessarily be over salted. In some cases, according to climate, the meat might be more mildly cured, perhaps, than it was, but that would render rapid consumption necessary. He thought Morgan's process gave promise of success; if they could effect in a few days a salting which required several weeks under the ordinary processes, it must be considered an advantage. In the curing of Irish bacon in the hot weather, the temperature of the curing-house was artificially cooled. In reply to further questions on the subject of Irish cured provisions, Mr. Grainger stated his opinion that Ireland could never enter into competition with America in the article of beef, even if it were sent to this country in a very slightly salted condition; the price obtainable for fresh meat would be a bar to such a competition; and from the injury which cattle were said to receive on the passage from Ireland, it was better, perhaps, to bring the meat over dead. The steam communication from Milford offered considerable facilities for the carcase meat trade with Ireland. No doubt the risks of injury to live-stock were considerable, sea and land passage having to be encountered. With the increased means of transit that were being developed at the present time, no doubt other sources of supply of meat to this country would be opened out. If Hungary had a railway system it would be capable of sending considerable quantities of meat to England, but they wanted the means of transit, and the cost by railway would probably not be more than ten per cent. The salt-beef trade from Ireland might be considered as extinguished. The live-meat market was open to them, and the prices were very much assimilated to those here. The agencies already at work were, in his opinion, sufficient to produce the most economical results that could be desired; and he thought there was no room for anything further to be done in that direction. The powerful agency of self-interest was at work amongst producers as well as consumers. He did not think it was possible to suggest anything that was practicable beyond what had been done already. In reply to further questions with regard to the adulteration of butter, Mr. Grainger expressed his opinion that no foreign substances were introduced into the butter sold in London and elsewhere, and the only adulteration was that of the salt pickle, which gave weight to the article and added to the profits of the producer, but that had been carried in some cases to an extent which defeated itself.

CANTOR LECTURES.

"ON POTTERY AND PORCELAIN." By W. CHAFFERS, Esq.

LECTURE VI.—MONDAY, MAY 13.

ENGLISH POTTERY.

Mr. Chaffers commenced his sixth lecture by alluding to the drinking vessels which were in use in England previously to the 16th century. They were of a very

coarse description, rudely fashioned, and usually devoid of ornament, but occasionally covered with a yellow or green glaze, and sometimes cast in a mould in grotesque forms. Numerous specimens of early English cups are found in the excavations made in the metropolis for the construction of sewers and large buildings, which may be, in many instances, identified by comparing them with the vessels depicted in mediæval manuscripts. But many other materials were used at the same period, and fashioned into drinking cups. The methar, a vessel made of wood, is frequently found in the bogs of Ireland, and, being of a square form, required some dexterity in drinking from without spilling its contents. In England the Peg tankard was much used in convivial parties. It was so called from a number of small pegs placed at equal distances to regulate the quantity to be taken by each person; these were frequently handsomely carved with religious subjects. Another description was the mazer bowl, so called from the German word *mäser*, signifying maple. Leather bottles, Venetian glass, cocoa-nuts, and other vessels constructed of a hard rind or shell, frequently mounted in silver, were also used. For plates and dishes a harder and more durable material was required, and wooden trenchers or pewter platters were generally in use. The vessels made in England were badly burned and not very durable, so that the German stone ware with a salt glaze was in general use throughout the 16th century, and was imported in large quantities. These stone pots were usually impressed in front with the arms of some German town, or other device, as a rose, &c., and under the spout was a ferocious bearded visage. They were derisively called "Bellarmines," after the celebrated Cardinal Bellarmine, who, in the 16th century, made himself so conspicuous by his zealous opposition to the reformed religion. It was not till the 17th century that stone ware pots were made in England of sufficient strength and cheapness to compete with those of Germany. In 1626 two Englishmen, named Rous and Cullyn, obtained the first patent for making stone pots and jugs, but, from their inferiority, the demand was not very great for them. The most successful imitation of the Grès de Cologne was made by John Dwight, of Fulham, which, in course of time, almost wholly superseded the importation of it from Germany. The Fulham stone-ware is frequently seen at the present day in collections; it is of exceedingly hard and close texture, ornamented with a blue or morone enamel in leaves and flowers, having in front medallions of the Kings and Queens of England, or their initials only. Mr. Chaffers alluded to a very interesting collection of specimens of the pottery made at Fulham, which were obtained by Mr. Baylis, of Prior's Bank, from a descendant of the Dwight family. Among these are some beautifully-modelled busts of Charles II. and James II., full-length figures of heathen deities, and various other objects, which show the perfection to which the manufacture had arrived. Dwight's first patent is dated 1671; at its expiration it was renewed for fourteen years longer. The next important pottery in England was at Lambeth, established about 1650, for the manufacture of Delft ware. The trade flourished here for more than a century, until about 1780, when the Staffordshire potters, by the great improvements they had made in the quality of their ware, and its cheapness, completely beat the Lambeth potters out of the field. Mr. Chaffers next passed in review the manufactures of Yorkshire. That of William Wedgwood, at Yarnsley, about the year 1700, was the earliest of which we have any record, but a century later the well-known Leeds ware was made by Messrs. Hartley, Greens and Co. It is of a cream-coloured glaze, with much perforated or basket work sharply cut round the borders. The other manufactories were at Castleford and Rotherham, but the most important was that at Swinton, under the patronage of the Marquis of Rockingham, established in 1757. The well-known

Rockingham teapot, of a chocolate colour, lined with white, had a great sale; but ornamental ware of a more artistic character was also made. Early in the 18th century Liverpool was the great centre for the manufacture of pottery, and in the first half of the century both fayence and porcelain were extensively made, both for home consumption and for exportation to the American colonies. About this time there was a large demand for punch bowls, and as these formed the principal ornaments on the side-boards of the middle classes, and especially on board the ships which were constantly going and coming in the port, considerable pains were bestowed in decorating them, and many are still preserved, painted with ships, convivial mottoes and descriptions, flowers, &c. The principal potters were Alderman Shaw, Mr. Richard Chaffers, and Messrs. Sadler and Green, the inventors of the method of transferring prints from copper-plates upon pottery, perfected in 1756, and of which Wedgwood, as well as many other potters, availed themselves to decorate their wares. Towards the end of the 18th century the trade gradually left the town, not being able to compete with Staffordshire in the prices, and only one establishment of any importance survived, viz., that called Herculaneum. Swansea was next noticed, established in 1750, its most flourishing period being in 1780, while under the management of Mr. George Haines; it was continued by Mr. Dillwyn. Some of the earlier ware is very elegant in form and of a deep-blue glaze, and is what was termed opaque porcelain, carefully painted with birds and flowers. The lecturer then alluded to the rude and coarsely-painted ware made in Staffordshire previously to the year 1700, the ornaments being merely coloured clays, direct and trailed over the surface through a quill; these colours were orange, white, and red, and glazed by means of lead ore beaten into dust and finely sifted and strewed over the surface. The vessels remained 24 hours in the kiln, and were sold principally to poor cratemen, who carried them at their backs all over the country for sale. The forms were dishes, tygs, or mugs with two or more handles for passing round a table, candlesticks, &c. The potter to whom Staffordshire owed great improvement in the manufacture of earthenware was John Philip Elers, from Holland, who, being a clever chemist, discovered the art of mixing the clays of the neighbourhood to great perfection. His imitations of the red ware of Japan, with leaves and other ornaments in relief, are well known. The various manufactories at Burslem, Bradwell, Shelton, Tunstall, and other places in "the potteries," and the gradual improvements in the composition and glazing of the ware, were adverted to in turn, illustrated by specimens which had been procured for the occasion, including the Staffordshire agate, marbled tortoise-shell, cabbage-leaf tea services, &c., made by Wheildon; the moulded ware of Enoch Wood; the close imitations of Wedgwood's jasper made by Turner, Adams, Neale, and others. The family of Wedgwood was of long standing at Burslem, and many members of it were engaged in making pottery long before the birth of the great potter, Josiah Wedgwood, which took place in 1730. He was the youngest of 13 children, his father dying when he was only nine years old; his eldest brother succeeded him, and took Josiah as an apprentice in 1744. During his apprenticeship he was seized with a violent attack of small pox, which left its effects in his system and settled in his leg, and an accidental bruise resulted in the amputation of his leg in the 34th year of his age. In 1754 he went into partnership with Thomas Wheildon, and he remained at Fenton for five years, after which he returned to Burslem and commenced business on his own account. Here he set himself earnestly to work, improving day by day in everything he undertook, and became so successful that he was compelled to enlarge his works, and he engaged the services of his cousin, Thomas Wedgwood, who in a few years became his partner in the "useful branch," especially the Queen's ware. In 1768 he took into partnership

Thomas Bentley, to whom was entrusted the "ornamental branch," both departments being kept distinct as far as the interests of his partners were concerned. In 1769 he opened a very extensive manufactory, which he called Etruria, and his first productions were copies of Etruscan vases, for which he took out a patent. In 1773 he made a fine white terra cotta, proper for cameos, portraits, and bas-reliefs. In 1776 the solid jasper ware was invented, in which Wedgwood largely employed sulphate of barytes, and for many years derived great profits from this, none of the workmen having any idea of the nature of the material upon which they were operating, until a letter containing a bill of parcels of a quantity of this article fell into the hands of a dishonest servant, who told the secret, and deprived the inventor of that particular source of emolument; for when the same article was made by those who employed inferior workmen, to whom they gave only one-fourth of the salary given by Wedgwood, the price became so reduced that he was unable to employ the exquisite modellers he had previously engaged. In 1780 his partner Bentley died, and the superintendence of the ornamental branch was given to Webber, a clever modeller, who, among other works, copied the celebrated Portland vase. Flaxman was engaged by Wedgwood and Bentley as early as 1776, and he continued furnishing them with designs and models up to the time of his departure for Rome in 1787, but after that he occasionally executed some models, and overlooked and gave finishing touches to the works of the Italian artists who were employed in copying subjects from the antique for Wedgwood at Rome. Josiah Wedgwood died on 3rd January, 1795. Some fine examples of Wedgwood's bas-reliefs in black basaltes and in jasper were exhibited. In conclusion, Mr. Chaffers remarked that the great improvements effected by Wedgwood may be best judged by a comparison with the works of the potters who immediately preceded him, many of which were on the table. Wedgwood not only in his "useful branch" displayed his aptitude for combining utility with neatness, and a certain degree of elegance, but in his "ornamental branch" he had a higher aim, which was to emulate the ancient potters of Greece, and in this he was ably assisted by his partner, Thomas Bentley. The lecturer referred his hearers who desired to be more fully informed upon the subject to his interesting work, "The Life and Works of Josiah Wedgwood," by Eliza Meteyard. The authoress had endeavoured to do all honour to his illustrious name, and with the materials she had gleaned from various sources (especially the manuscripts in Mr. Mayer's possession) had, with untiring energy and zeal, fulfilled the task of a faithful biographer.

TWENTY-SECOND ORDINARY MEETING.

Wednesday, May 15th, 1867; W. H. ALTON, Esq., in the Chair.

The following candidates were proposed for election as members of the Society:—

Committee, Lieut.-Col. Louis, R.E., Golden Cross Hotel, Charing-cross, S.W.
 Messrs. Frederick, 26, Maddox-street, Regent-street, W.
 Mr. J. W. In, Anthony, 4, Adam-street, Adelphi, W.C.
 Mr. J. H. Hitley, Nicholas, Truro, Cornwall.
 Mr. J. Williams, Michael, 35, St. James's-place, St. James's-street, S.W.

The following candidate was balloted for, and duly elected a member of the Society:

Mr. J. H. Nichelo, George, 14, Barnley-road, Stockwell, S.

The Paper read was—

ON NEW MACHINERY FOR CUTTING, TUNNELLING, QUARRYING, AND FACING SLATE, STONE, AND MARBLES.

By W. FOTHERGILL COOKE, Esq.

"Coctitibus muris cinixisse Semiramis urbem."
 Semiramis is said to have surrounded the city with burnt-brick walls.

Such was the defensive material for fortifications in the days of Semiramis; and the grand old temples and palaces of Nineveh, thinly coated with richly sculptured slabs of limestone, or precious marbles overbricks (burnt or unburnt), stood forth with well-contrasted grandeur and apparent solidity. The Romans and the Lugdunenses of their day, conjointly reversed the practice; and whilst the Roman general fortified the city with stone ramparts, the London citizens raised their habitations in fiery red bricks.

Stone is scarce, whilst clay is still abundant in the precincts of London; and sea-borne coal cheaply converts the subsoil into the most handy of building materials. Not only is stone scarce, and expensive in the rough block, but the finished and ornamental working of it is most costly, and even a thin casing of stone adds from fifty to seventy-five per cent. to the architect's estimate for a frontage alone.

I trust this evening to introduce to my hearers some novelties in the machinery for cutting rock, and working stone for ornamental purposes, which may encourage our architects and builders to adopt stone, instead of London brick and Roman cement, in their future elevations, and thus open up a prospect of a better architectural future for at least our western streets and mansions.

Stone, of good building qualities and easily worked, is abundant in many parts of Great Britain; and the charges of carriage by canal, rail, and sea would not materially affect its use in the better class of buildings, if it could be worked more economically, and sent up in a quite, or nearly finished state from the quarry.

A class of stone rarely or never seen, I believe, in London buildings, but much used in the best buildings in North Wales and some parts of England, the tertiary limestone, is very durable and cheap, and takes an excellent face, almost approaching to a polish, under the new tool. Sandstones, Portland, Caen, and Bath stone, are all much softer and mostly less durable than limestone, but not more easily worked.

Machinery, which has been so widely applied to other trades, has hitherto done but little for masonry, though in this remark I confine myself to masonry proper, not including sculpturing by machinery. Except by the sand-saw, and occasionally by the circular toothed-saw, stone has hitherto been worked chiefly by hand. I wish here to remark that the harder stones, including the granites and granite-like rocks, cannot be operated upon by this machinery at all. This machinery, which I will now proceed to describe, depends chiefly for its efficacy on the peculiar forms of the cutting tools or movable teeth; firstly, in the application of them as attached to holders or sockets fixed in the edges of the blade, instead of the blade itself forming the cutting edge; and secondly, as applied to the circumference of cylinders for surfacing. The tools, or cutting-teeth, are, in consequence of their being movable in the sockets, easily replaced as required without any reduction of the diameter of the blade, which so soon renders the circular saw, when applied to the cutting of stone or slate, useless. These movable tools or teeth are capable of application to machinery for a variety of purposes, firstly, to the sawing of blocks and slabs of rock of considerable thickness, for building or other purposes; secondly, for facing the surface of squared-up stones in an ornamental manner; thirdly, for tunnelling, for undercutting stone, slate, or coal in situ, where the rock lies more or less on the incline, and also for the vertical cutting of the living rock almost as readily as a haycutter cuts hay out of a stack. These movable tools, held in movable sockets, are, as I have said, the distinctive features of this

machinery, and they are exclusively the invention of Mr. George Hunter (now of Maentwrog, North Wales).

"Hunter's saws," with the improvements which have rendered them so effective for many purposes, are becoming well-known in the United Kingdom. They are extensively used in North Wales; and last autumn Mr. Hunter put up one at South Shields, for the Commissioners of the Tyne Navigation. The diameter of the blades in this saw is seven feet, and it carries two blades on the axle. It is employed to cut the limestone of the neighbourhood for the Harbour works. The performance of this saw gave such satisfaction that a second was speedily ordered, to carry two blades of thirteen feet diameter each. This gigantic machine is now finished, and will be speedily at work upon the same limestone. Its depth of cut is over five feet. As there is no reason why the thirteen feet saw should not work as easily as those of seven feet, the success of this machine will, I feel confident, attract the attention of engineers and contractors to the desirability of this means of squaring large stones for harbour and similar purposes, where size, economy, and time, are always of leading importance.

As it is known to many now present that my own name is united with Mr. Hunter's in several recent patents, I will observe that my share has chiefly consisted in extending the application of the movable tools and tool-holders (the real essence of his invention) to fresh and wider fields of usefulness, whilst the onus of adapting the machinery to each novel application, and in so doing producing an entirely new result, has fallen upon the inventive genius and mechanical skill of Mr. George Hunter.

Fig. 1 represents the movable cutting tool, now most in use, fixed in its holder or socket. It is a bolt made of the best rod steel; the head is forged into a cupped or trumpet form—turned, and then hardened. When in use it is simply slipped into its socket, which is also made of steel, and wedged tight by a piece of paper or a thin shaving of wood. When the edge is dulled or chipped the tool is turned in its socket so as to offer a fresh cutting margin: and, as it wears away chiefly on the advancing side, the tool will generally offer three, sometimes four fresh surfaces before it is worn out. These tools, according to the circumference

of the saw blade, are from four to eight inches long; the cutting head itself from half an inch to one and a quarter inch wide. The length of the bolt allows

FIG. 1.

the tool being softened, again set up, turned, and hardened, until it is too short for further use.

The stems of the sockets are of the same thickness as the blades that receive them, and are slipped into grooved openings in the margin of the blades, which they are fitted with accuracy by machinery. As

FIG. 2.

blades revolve slowly, the tools are usually replaced, merely turned round in their sockets when necessary, without stopping the machine, and should thus be

FIG. 3.

ways in good cutting order. The cupping, shaping, and tempering of these tools require modification in each case, to adapt them to the texture of different kinds of stone. Limestone and sandstone, for example, cut away in large chips, whilst slate has to be scraped away, and the tool must be made to suit each case.

The next tool (see Fig. 2) to which I will direct your attention is formed by the double action of a punch. The first action cuts out a round disc from a plate of steel, like the punching of a boiler plate; the second action converts the disc into a tool, precisely similar to the head of the bolt-like tool just described, only ready cupped and sharpened, with a boss behind, to fit into a corresponding groove in the back of its holder, and with a hollow in front for a nipping bolt, or pinching screw, to grip it (see Fig. 3). These discs, so punched into the exact form required, only need tempering to be at once fit for use. The older of the disc-tool grasps it between (as it were) its finger and thumb with perfect firmness, and as the cutting rim projects only very slightly beyond the older, it offers very little leverage to the resistance of the stone, and never gets loose or displaced. Either of these forms of tools may frequently be used for the same object, but each has its specific application as well.

I must now introduce you to another form of tool (Fig. 4), equally simple in its character with the last, but peculiar

FIG. 4.

in its adaptation to a distinct purpose. It is formed out of a symmetrical, acute-angled trapezium, cut from a ribband of steel, two or three sixteenths of an inch thick, according to the roughness of the work it has to do. To convert these slips of steel into the required form of tool, they are bent sharply on their middle, so as to bring the acute angles opposite to each other, but slightly turned out at their cutting angles.

These tools are cut from the ribbands of steel without any waste, and if not left sufficiently sharp by the shears, a number of the flat slips are screwed up together in the vice, and sharpened by the file; they are then bent and hardened, and are fit for use.

The socket for this form of tool is extremely simple (Fig. 5); it is merely a hole into which the tool slips, and in which it is held by the spring of its own arms. The chief use of this tool will be the roughing down grindstones, and scarifying the rough surface of slate and stones, preparatory to the facing tool, and it is, perhaps, the best form of tool for under-cutting coal.

In addition to those already described, there are flat, concave, and other formed tools, all adapted to the holders, for giving ornamental and apparently hand-

tooled surfaces to ashlers, quoins, sills, &c.; but as I shall have occasion presently to call further attention to them, when speaking of ornamental mouldings in machine-worked stone, I will not here dwell upon the subject.

I now turn to the application of these simple, cheap, and effective weapons to various forms of machinery:—

First in order comes the "Hunter's saw."

The diagram attached (Fig. 6) is so clear that it almost tells its own tale; it is taken from the small hand model upon the table. In the mechanism of the machine itself there is but little novelty, and it may be worked by any suitable power.

It consists of a table moving on V grooves, or on friction pulleys, to which the stone to be cut is fixed by cramps, or, when very massive and rough, as at New-castle, by chains. The table is fed forward by a self-acting screw, and advances upon the cutting-blades at a speed of from three to six inches per minute; the speed varying with the work to be done and the nature of the stone. The cutting-blades, running from one to four in number, are fixed to collars, which traverse on an axle above the table, supported by uprights, and moved by a train of wheels in the usual manner. For adjusting the width, pinching screws in the collar of the cutters are slackened, and the blades are then pushed or worked by ratchet along the axle, and can thus be set apart to correspond with the width of any stone that the table can carry.

FIG. 6.

In Fig. 6, as well as in the foregoing description, the saw-blades are represented as working above the table, but they are not necessarily, or always so placed, except when the stone or slate to be cut into slabs or blocks is of variable widths, and the blades have to be moved on the axle to correspond therewith. When the blades are above the table the tools are made to cut up-

FIG. 5.

wards from below, by which the working of the machine is eased, as each tool slides smoothly at first into the groove formed by the preceding tool, and then cuts boldly out at the top of the slab in its own new path. But, when the blades are carried on an axle below the table, the cut must be from above downwards. If these arrangements are reversed, the tools will come *aplomb* on the stone with a jarring blow, and tend to drag it into the cutter, when the result may be the crumpling of the blade, or the stripping off of the tools from their holders.

Before leaving this machine I will state that, for cutting window-sills, door-posts, steps, coping-stones, and a host of other building materials, out of rough blocks of slate—which were formerly necessarily thrown away as useless, because there was no means of working them—we employ now three or four blades of four feet diameter, all cutting at the same time upon the same axle. These blocks, frequently twelve to sixteen inches thick, and weighing several tons, are simultaneously reduced to five thick slices, and immediately split up into the required thicknesses for planing, or tooling, as most suitable. An immense amount of paying work is thus turned out of rock, formerly all thrown away, and still accumulating by thousands of tons yearly on some of the giant and wasteful rubbish heaps of the Welsh slate quarries. At quarries in which I have a considerable interest there are now three, and will shortly be seven, saw-tables of large dimensions in busy and productive work—converting everything of value into slates, slabs, or building materials.

Under a recent improvement we use a succession of tables always advancing, on which the blocks are prepared before the saw is ready for them, which saves the time of running back the table, unloading, and preparing another block. Thus, so soon as the first cut is completed, the saw-blades are re-adjusted for the next block, the first table is brought on, and at once passes forward under a crane, where the block is re-adjusted for the next cuts, or, when finished, removed to be split up for the planes, and the table is either sent forward to the next saw with a fresh load, or lifted by the crane on to a line of rails parallel to the series of saws, and run back to commence its course again.

The next application of the movable cutting tools which I will describe differs but little in principle from the last, but is productive of very different results. The axle of the cutters is still above the table, but capable of being raised or lowered, as the cutting tools are in the ordinary engineer's plane. Instead of two or more blades fixed on their sliding collars, carrying an array of cutting tools on their peripheries, as in the saw, the axle itself, or a removable cylinder slipped on, or bolted in halves to the axle, receives the tools.

The object of the machine now under consideration is to give a finished surface to building or other stone of a more or less ornamental character; and breadth not depth has to be cut. The tools are fixed in holders, placed spirally round the axle or cylinder, so that a divided and regular pressure may come upon the face of the stone at intervals of two or three inches, always nearly uniform, but ever passing spirally from right to left. In the specimens of ashler shown, the tools formed one spiral, each fourth tool cutting at the same time, and six tools were entering into the cut as other six were leaving. A double spiral, in which the tools followed each other more closely in their cut, would have given more uniformity of strain, but could hardly have produced a more perfect piece of work. The fluting here produced may be varied without limit, or, the margin work cut by the flattening tool may be carried over the whole surface. By the introduction of a second cylinder, the beginning and end of each stone will receive a border across the stone corresponding to the long margin of whatever pattern it may be. For fluting or similar work the punched tools have a great advantage, whether of the disc or flat-faced form, as they are

always of exactly the same diameter, and produce uniform work. The marginal tool may cut off a chamfer if required.

Anything that parallel working tools on a revolving axle can execute, will be done readily by this machine, and on a larger cylinder tools of a different shape may work along the same line so as to vary a running figure, by alternate markings. In fact, the outline of work thus produced seems unlimited, and ornamental figures, that this machinery cannot complete, may yet be prepared by it in outline ready for the sculptor's hand. Take the instance of a Gothic church window. The perpendiculars would be easily cut out in any running pattern, on a straight moving table, by a series of tools corresponding in their forms to the required surface. These tools would be fixed on a cylinder cast more or less in reverse of the same outline; but the same lines round the arch would render it necessary that the table carrying the stone should travel along rails or grooves, bent accurately to the curvilinear line required for each particular arch.

These hints will readily expand themselves in the mind of every practical man. Many figures more difficult than the above have already been considered, and the means of execution planned.

The roughing tool before described can be made to imitate the marks of a pickaxe in rustic stone work with the usually chiseled work around it.

The table for carrying the stones to be faced in continuous lines has hitherto been supposed to be the same as that used for sawing or planing ordinary slates, but when quoin or other stones of irregular dimensions and great size have to be treated, a distinct table, with a skeleton cradle, either movable or fixed, is necessary to receive the blocks, and offer the upper surface of the stone horizontally to the facing cylinder. The irregular-shaped block thus placed is fixed by pinching-screws or wedges, and the depth of cut is regulated by the lifting-tool gear as in a common plane.

Some of the patterns of flat tooling by these machines can be made to imitate chisel-work so closely as to be distinguishable alone by the finer finish given by the machine. The shortness and sharpness of the tool-cut are regulated by the diameter of the axle, the number of cutters, and the rate of feed. The finer kinds of limestone, including especially those of the Isle of Anglessea, receive almost a polish from the cutters. These machines will be of moderate weight except when required for the facing of massive blocks, and a very small power works them, so that they could be sent about the country to prepare the stones for a building on the spot, where an equivalent complement of masons could only be obtained by collecting them from great distances.

I will now describe the machines for cutting stone, &c., out of the living rock in the quarry itself. The principle here is, I believe, new. The cutting tools, instead of being placed in a single row around the rim of a thin blade, are fixed in rows of twos and threes alternately across the margin of a wheel-like disc, so as to clear away a wider space. The outer portion of this wheel-like disc is a ring of fine malleable cast-iron armed on the out-side with tools, and carrying a cog-wheel within. Not to enter into small details of fittings, this cogged wheel is made to revolve on a broad metal plate as its axle. This broad plate is of great strength, and forms four-fifths of the diameter of the entire cutter, and can be firmly bolted to the machinery frame by any part of its surface nearest to the cogged wheel which carries the tools, and the latter so held is made to revolve by a pinion around it. This arrangement allows eccentrically-held cutters to penetrate the rock to a depth exceeding the semi-diameter of the disc. In the circular saw with a central axle, the blade can only penetrate to so much of its semi-diameter as is clear of the axle and collar, and great force would be required to hold such a cutter up to its work in the rock, but in the machine now

before us, the cutter-wheel is buried in the cut up to the point at which it is held, and practically allows of a cutter of 3 ft. 4 in. diameter burying itself to the depth of 2 ft. 3 in., and as the cutter cuts out at a chord smaller than the diameter, the tendency of the out-coming tools is to draw the cutter into the cut, instead of forcing it out. A machine of this kind, cutting horizontally, works with great freedom, and advances rapidly through slate rock upon which it is employed. But when a cutting wheel on this principle is applied to make a vertical cut, a still smaller surface of the broad-axe plate is occupied by the holder, as it can in that position be grasped on both sides, and the axle, carrying the pinion, can be passed through the wheel and supported upon double bearings.

The machinery, including the cutter-wheel, for vertical cutting, is fixed on a carriage running upon rails, and worked by a wire rope. The cutter-wheel is gradually brought down from its travelling position by a worm and worm-wheel to press upon the rock till it buries itself up to the holder, when it is fed forward by a self-working screw, attached by chain and swivel to some point in advance, or by winding directly upon a chain.

A tolerable level having been first obtained on the face of the quarry, and a line of rails pinned down in the direction of the cut to be made across the greatest length, the machine commences its advance, leaving a deep groove behind it two or three inches wide, and two, three, or four feet deep. A series of parallel cuts may afterwards be made, or two disc cutters on the same carriage frame may be advantageously used to make two cuts at a time. An opening at the commencement of the first cut end must then be got out by blasting or otherwise, but afterwards, if the rock has any sort of cleavage, or layering, it may be wedged up from below. The rock from between the first two cuts being thus removed, the vertical cutter may readily be applied to cross-cut the longitudinal grooves into squared blocks, to be removed by under wedging, or partial undercutting, when there is not a favourable cleavage. The principle of the "under-cutting" machine is precisely the same as that of the vertical cutter. The cutter plate, however, has to be held horizontally by one side only. The cutter lies under the frame that carries it, and is advanced into its cut by worm-screw and worm-wheel as already described. When buried up to its holder in the rock, the cutter traverses along a slide frame twelve feet long; at the end of the twelve feet the slide and its carriage frame are pushed forward on the wheels for another length, and there fixed so as to leave the cutter free in its previous cut; it again proceeds on its journey, fed forward by its self-feeding screw, and so on to the end of the opening. The photographs of this machine exhibit all the details of its construction, which cannot be popularly explained without illustrations. The exposed parts of all these machines are very strong, and although shattered pieces of rock coming down upon the cutter-disc may momentarily impede its working, no injury to the machinery follows. The masses of stone cannot crush the disc, and the power employed in working the machine is not sufficient to break the wheel-work.

There are other applications of these movable cutters which I would gladly have introduced to the attention of the Society this evening, especially the coal-cutter, but the time allotted is too short for my venturing upon them on the present occasion. There are some photographs, however, which display the formidable character of the tunnelling machines. One form includes in its construction two parallel borers, cutting two tunnels each 5 ft. 4 in. in diameter, side by side, and freeing two cores weighing more than two tons each at every cut. The slab of slate, still marked at its ends by the cutting tools, indicates the size of the pieces of slate that may be won by it. From one core, and that one the first ever cut by that machine, 23 slabs of more than one ton in weight were made, besides a considerable number of slates. Its rate of progress in cutting is eight inches

per hour, and the depth of cut allowed by the cutting-blades is twenty-one inches forward. This machine has penetrated many yards into the solid slate bed, and is destined, I fully believe, to revolutionise the present system of quarrying that valuable material.

Other photographs represent another form of the tunneller, which is now being erected in a quarry of the Ffestiniog Valley. It will cut a single tunnel six feet nine inches in diameter, and penetrate twenty-eight inches at each cut. The principle explained in the "under-cutting" machine is employed here, only the solid central holder, for the axle-plate, is here open in the centre as a ring, round which the cog-toothed cutter-ring revolves; and the latter, instead of carrying the movable tools on its periphery, in the same plane, carries three segment blades of steel, projecting forward, at the extremity of which a series of cutting tools are fixed, as in the saw-blades. The carriage of this machine is fixed in the tunnel immovably by bolt-screws, and the massive working parts gradually screw themselves forward as the cutters penetrate the rock. The open passage is preserved through the centre of the ring-frame and ring-cutter, to the front of the work, even whilst the machine is in action; owing to this, the core, after cleaving up, is more readily removed than from the double tunnelling machine. This machine will excavate more than five tons at a cut.

A high authority in engineering has lately condemned this principle of "planing" out a rim round a core as a mistake. I hope before the end of this month to prove, by a second marvellous success with a second machine, that practice is better than theory.

Five feet to 6 feet 9 inches will be no trifling advance in a second tunnelling machine; but a much larger diameter for mere tunnel driving will only facilitate its working, as it will admit of more space for strength. At all events, this machine admits of the greatest facility for replacing the tools, if blunted or worn by encountering hard matter in the rock. The feeding screw is simply run back, and the tools are examined and replaced without removing the framework from its fixed position. Generally the tools retain their sharpness throughout the cut. It must be remembered that these machines were made expressly for slate rock tunnelling, and have not yet been tried on sandstone or limestone rock for tunnelling purposes, which may offer fresh difficulties, only, I hope, to be mastered, and the usual means, perseverance and resolution, never fail us in this country.

The following are the dimensions and weights of parts of the great circular saw with thirteen-foot blades, now being erected near Newcastle for the Tyne Navigation Commissioners, by Mr. George Hunter:—Shaft, 15½ inches diameter; weight, 3 tons; driving-wheel, 3 tons; standards, 3 tons each; saw-blades with collars, 3 tons 2 cwt.; height above floor, 17 feet; cut, 5 feet 6 inches; width of cut, 1½ inches; speed of tools, 18 feet per minute; feed of table for cut, 3 inches forward per minute; width between standards, 14 feet.

DISCUSSION.

Mr. BOTLY said they were very much indebted to Mr. Cooke for the very excellent paper to which they had listened, for to their Society anything which tended to economise labour and material must always be interesting. He had the pleasure of making a tour in North Wales in September last, when he had an opportunity of inspecting several of the slate quarries there. Some of these appeared, in his opinion, to be worked in a very slovenly manner. One thing he particularly noticed, which had been mentioned by Mr. Cooke, viz., the enormous waste of slate, especially in blasting. Large masses were wasted by the system of quarrying there adopted, and he apprehended, from the description of the machine, that a great saving might be made by its use.

Mr. R. G. LUCKY had much pleasure in bearing his testimony to the value of the machines, having recently

seen one at work. There were many points in it much to be admired, especially the facility for sharpening the tools, and the power of the saws to cut deeper than their semi-diameter, which was a great fault with common saws. He was able to speak to that point, because about 15 or 16 years ago he had helped to plan, construct, and erect, what he believed was the largest slate saw ever made up to that time. It was for the Valentia quarries, and was capable of cutting nine inches of Valentia slate, which was pretty hard. Working with two 3 ft. 6 in. saws on one axle, they were able to cut nine-inch slabs at the rate of about five feet an hour, and this was considered pretty good work. He thought, therefore, that Mr. Cooke had spoken a little too depreciatingly of the working of toothed saws. These saws certainly lasted a very long time, for one pair had been at work for six months or more, and only required sharpening once a day. The blades were $\frac{1}{2}$ inch thick, and there was one-eighth set on each side, so that the breadth of the cut was half an inch. It was much easier to work these two saws than to work a single-bladed hand-saw. He believed these saws were still at work at Valentia. Hunter's saw, however, was a most efficient machine, and he was very much pleased with it.

Mr. C. F. VARLEY said that about two years ago he paid a visit to the neighbourhood which Mr. Cooke had described, and he had spent a considerable time in the quarries known as Lord Palmerston's, which he believed yielded the best slates to be found in that part of the world. The first thing which struck him was the mountains—not merely hills—of waste. It was something prodigious; in fact, he believed he was correct in saying that only about one-ninth of the slate got out of the quarry was ever brought into the market in the form of slabs or roofing slates, and that under the most favourable circumstances, when they had obtained large and sound blocks, they never succeeded in making more than one-fourth of the material so extracted available for commercial purposes. The process of tunnelling, which Mr. Cooke had particularly alluded to, seemed a very important one. It was necessary to form tunnels through the slate to get from section to section, and as in so doing they undercut the mountain, it was requisite to leave strong pillars to support the superincumbent portion, and all this had to be done before getting at the slate. It was therefore evident that if this tunnel took such an enormous time to cut—Mr. Cooke had mentioned ten yards a month—there must be a large amount of capital lying idle in such a quarry for a considerable time before any returns were made. Anything, therefore, which would quicken these preliminary operations must be very valuable, and he understood from Mr. Cooke that the tunnelling machine would do the work three-and-a-half or four times as quickly as it could be done by the old method. The combination of the circular cutter and the under cutter, by which pieces of slate were brought out ready for immediate working, seemed also very valuable, and he had been informed that in this way rather more than one-half of the whole amount of slate taken from the quarry had been actually rendered available for the market. That alone showed the immense value of the machines which Messrs. Hunter and Cooke had already brought into successful operation. The photographs which were exhibited showed that several little difficulties which had presented themselves when he was in the neighbourhood had since been mastered, and he saw no reason why the machines should not meet with all the success which had been hoped for them, especially since the cutters could be made in so simple a manner, so rapidly, and at so trifling a cost. These little circular discs were nearly the only parts of the machine which underwent any serious wear and tear, and these were stamped out so quickly that the only parts of the machine likely to wear—the teeth of the saw—were rendered the cheapest to construct, and not only this, but they were so simply and easily taken out and replaced that it took only about ten seconds

to remove a damaged one and substitute a new one, the cost being, he should imagine, a very small fraction of a penny. All this, too, could be done without withdrawing the machine from its work. That he considered one of the greatest improvements. The application of the cutting machinery to the working of the stone seemed, however, to his mind, even more important than that which he had referred to, the mere cutting out of the plate, as it superseded the necessity for the enormous amount of hand-labour now employed in cutting and dressing stone. There was another point of view from which it seemed to him that the invention ought to receive the especial approval of the Society. For many years, especially under the presidency of the Franz Consort, great attention had been paid to improvements in buildings for the poorer classes, and also to familiarizing the public eye with articles of artistic design. One of the specimens on the table, to which Mr. Cooke had not drawn attention, was a piece of a ridge-tile, a size, and in that it would be seen that, simply by one of the of the machine being placed rather more prominently than the others, an effect very similar to what was done when engine-turning had been produced, an effect which could not be produced by hand except at an immense cost. In the same way, it was evident that, by slightly varying the position of the tools, almost any design in moulding in stone might be produced. He believed that Mr. Cooke had done for stone that which was done many years ago for wood, and that material which before was of small value, but of costly manufacture, was now easy to be worked, and would, therefore, be produced in great abundance and at low cost; so that stone would begin to take the place of brick in very many instances.

Mr. COOKE, in reply to the questions and observations which had been addressed to him, said he feared that great waste from blasting would never be diminished in some of the great quarries. The floors were not so deep, however, as had been imagined; the deepest, with very few exceptions, were about 60 feet. In one or two instances, perhaps, the depth might be 90 feet. The practice which had been adopted there for some time was to bore a hole 14 or 15 feet in depth and 2 inches or 2½ inches in diameter, and charge it with powder, explosive glycerine, or cotton, and so bring down an enormous mass of slate, which, perhaps, would take three months in removing. He had seen, at Mr. Ambrose Smith's quarry, a mass of slate which had not been entirely removed at a second visit, four months later. With such a quantity falling such a height, of course an immense amount was damaged, and not more than one-ninth, or sometimes a tenth, was fit for the market. He believed the proprietors would do well to introduce these machines, and thus effect a great saving. They had sometimes sent him pieces to cut, and a short time since he received a block of about four tons, which he returned in about half-an-hour, cut into fine slabs. Nothing could have been made of it without the machine, as some parts were very hard, and there was no good cleavage. He was afraid, however, that the wasteful system would continue for some time in the large quarries, where the owners, being wealthy men, looked for a large and rapid return, although such a mode of procedure must tend to exhaust the material; and he believed that one quarry at Penrhyn was already causing the proprietor some anxiety. He had been much interested in hearing from Mr. Lecky of the Valentia saw, which was new to him, or he should certainly have referred to it in the paper. He would like to know the speed at which it worked. The ordinary speed of their small saws was 120 ft. to 130 ft. a minute.

Mr. LECKY said the Valentia saw was driven at a speed of nine revolutions a minute, or about 108 ft.

Mr. COOKE said that their machines worked at only 45 ft. per minute. He believed the Valentia stone was very valuable, but that it was not a slate, and had no cleavage, being only valuable for slabs, and not for roofing slates.

Mr. LUCKY said the stone was a true slate, and had a decided cleavage, though the softer portions would only leave into very thick roofing-slates. The slabs were cut with hand-saws.

Mr. COOKE said that appeared to be a slate which wore the saws very little, for at the Ffestiniog quarries he had seen a saw removed twice in a day to be sharpened, and had known one worn out in the course of a fortnight. The work done by the Valentia saws was very good, and although there would be more waste, the comparative cost of the machinery at starting would, probably, in that instance, be in favour of the saws. He considered the small disc tool a perfect masterpiece, and the cost of each would certainly be a small fraction of a farthing. The ornamental work to which Mr. Varley had called attention arose from an accident; one of the tools being rather larger than the others, every time it came round it made one of those curves. Of course no one could see that without seeing that the same thing might be turned to advantage, and there was no doubt that the tools could be so arranged as to produce on the stone every effect of engine turning.

Mr. BLACKIE observed that the cost of the machines had not been stated, or the cost of erecting them, and what was the percentage of wear and tear, which, he imagined, must be considerable. He should also like to know what power was used to drive them, and the amount of horse-power required for a large machine.

Mr. COOKE said that, in the case of one of the machines which had been in operation two or three years, it had not yet shown any symptoms of wear and tear; it was difficult to form a calculation, but the part which seemed to wear most was the nut which worked the feed-screw; the dirt got in there and wore away the brass. The cost of the machines varied from £100 to £1,500; those were the two limits.

Mr. BLACKIE suggested that if cups were applied over the bearings and parts where dust was likely to fall, it would save wear, and remarked that no information was given as to the temper of the tools, and whether water or any other liquid was used in cutting the stone. It appeared to him that, whatever might be the temper of the tools, if they were worked dry, the friction and consequent heat would be so great as very quickly to destroy them.

Mr. COOKE said the machines worked so slowly that unless when cutting something particularly hard, like quartz or iron pyrites, the tools did not heat in the slightest degree. On one occasion, in cutting through some iron pyrites, he had found the tools not only hot but actually melting. Such cases were very exceptional, and must be dealt with when they occurred. With the circular form of tool, it was easily turned round with the finger as it came up, so as to present a fresh edge, and each tool gave them three cuts before it was worn out, and the largest of these tools would not cost certainly more than a farthing. There was a great difference of opinion amongst the workmen in Wales as to the merits of dry or wet cutting; in some quarries, where there were a great many circular saws at work, the men liked to use water, and in others they did not. In his (Mr. Cooke's) quarries they invariably used water in tunnelling, both to keep the tools cool and to wash out the *débris*. They worked the double-tunnelling machine with a small turbine, and some of the water, before it reached the turbine, was sent through a tube into the cutting, so that the tools were kept quite cool, and he had seen them go in for a second cut without turning, and that in bad slate, where there was a good deal of iron pyrites. With regard to the temper, he had already mentioned that it varied according to the stone to be cut. They did not send slate tools to Newcastle to cut limestone; a very inferior tool would do for that work. Nothing was worse to cut than sandstone or slate. The sandstone yielded too soon and ground the tool, and the slate also would always grind it. It would take a considerable time to

grind the hard edge of the tool off, but when that was gone it was soon finished. Only the day before a mason had been looking at the various specimens of work on the table, and he at once observed that a different tool would be required for each. Marble would very soon destroy the edge of a tool if used dry, but if abundance of water were used nothing cut more easily, and a fine polish was left; it was like turning brass with oil, or iron with water, if they were turned dry the tool would very soon be spoiled.

Mr. BLACKIE suggested that the powdered stone which resulted from the cutting would be valuable for mixing with lime, in parts of the country where sand was not easily obtainable.

Mr. COOKE said this was a very good suggestion.

The CHAIRMAN then moved that a cordial vote of thanks be given to Mr. Cooke for the paper which he had brought before them. The machinery he had described seemed likely to prevent the waste of material of considerable value, and was certainly most ingenious.

The vote of thanks was then passed.

Mr. Cooke illustrated the action of his machinery by a working model, and a large number of specimens, showing the effect of the various tools described in his paper.

THE ROYAL COMMISSION ON RAILWAYS.

The Royal commissioners on railways have at length made their report, which sums up in great detail the results arrived at from the mass of evidence adduced before the commission, and gives judgment against the proposition that the railway system should be taken under the control of the state. The general conclusion of the commissioners is, in short, that no comprehensive plan shall be undertaken, and that the dealing with the railway system shall be confined to private-bill legislation and in the management by companies. The report says:—

"We are of opinion that it is inexpedient at present to subvert the policy which has hitherto been adopted of leaving the construction and management of railways to the free enterprise of the people, under such conditions as parliament may think fit to impose for the general welfare of the public.

"We consider that there is not sufficient reason for excepting Ireland from this general conclusion; but, as it has always been the established policy to assist railways and other public works in Ireland, we recommend that, when parliament thinks fit to make advances to Irish railway companies, the money should be lent for a fixed period of considerable length, so as to enable the company to develop its resources before it is called on for repayment. We are, however, of opinion, that advances should not be made to the Irish railway companies as a condition of reducing their rates and fares; but that, as the railway companies have the best opportunities of judging whether rates can be reduced so as to be recuperative within a reasonable time, they should be left to carry out such experiments at their own risk.

"We recommend that parliament should relieve itself from all interference with the incorporation and the financial affairs of railway companies, leaving such matters to be dealt with under the Joint-stock Companies Act, and should limit its own action to regulating the construction of the line and the relations between the public and joint-stock companies so incorporated, requiring such guarantee as may be necessary for the purpose of securing the due performance of the conditions upon the faith of which the parliamentary powers of the company have been granted.

"We do not consider that it would be expedient, even if it were practicable, to adopt any legislation which would abolish the freedom railway companies enjoy of charging what sum they deem expedient within their maximum rates, when properly defined, limited as that

freedom is by the conditions of the Traffic Act; but we are of opinion that railway companies should be required to give a reasonable notice of their intention to raise their rates of charge.

"We are unable to see any method of ensuring punctuality in passenger trains by means of legislative enactments, except that proposed by the committee of the House of Commons in 1858—viz., that punctuality should be guaranteed, and that passengers injured by delay should be enabled to recover summarily a fixed sum; but we have already referred to the objections to this proposal.

"We are of opinion that railway companies should be bound, under adequate penalties, to give at least a week's notice of any alterations of time of their regular passenger trains.

"We do not consider that any direct legislative enactments would cause greater economy in the working of railways; but we are of opinion that, with the object of affording a more accurate view of the operations of the railway companies, and of making any undue extravagance apparent, and thus stimulating economy, it is desirable that the several railway companies should render their accounts to the Board of Trade, showing receipts from traffic and the detailed cost of working the line, upon a uniform plan; and that, after consultation with the railway companies, the Board of Trade should not only prescribe the form of such returns and accounts, but lay down the basis on which they are to be computed.

"Parliament has relied, for the safe working of railways, upon the efficiency of the common law and of Lord Campbell's Act, which give persons injured, and near relatives of persons killed, a right to compensation. We consider that this course has been more conducive to the protection of the public than if the Board had been empowered to interfere in the detailed arrangements for working the traffic."

Fine Arts.

EXHIBITION IN PARIS OF THE PRODUCTS OF THE PUBLIC SCHOOLS OF ART.—The Minister of Public Instruction has determined upon establishing a general exhibition of works of art of all kinds produced in the Art Schools of the State, and has devoted the terrace of his mansion to the purpose. Three galleries, which will be finished in a few days, will be appropriated as follows:—In one will be specimens of modelling, architectural works, casts in plaster, plans, linear drawings, ornaments, stereotomic models, and mathematical and philosophical instruments. The central gallery will be devoted to drawings, engravings, lithographs, and photography; and in the centre will be an exhibition of needle-work, lace making, application, embroidery, and other works produced by the pupils of the female schools. The third gallery is intended for a different purpose, namely, the exhibition of objects of value and interest, brought from Mexico by the Scientific Mission, with a systematic collection of ores and minerals made in Mexico, and a number of statuettes of divinities of past times, and other works of art.

Manufactures.

CENTRIFUGAL GUN.—Dr. Steinheil, Professor of Natural Philosophy at the University of Munich, well known in the scientific world for having laid down an electric telegraph at a very early date, has invented a gun, which is thus described by one of the *Times* correspondents:—"Figure to yourself an iron plate of a circular shape, sunk in the middle. This cavity is filled with balls, which, on the plate being set in motion, are propelled along a groove radiating to the edge, where

they are received into one or several barrels made to point to the object aimed at. The centrifugal force with which they leave the disc, being on mathematical principles 12 times as great as the celerity attained by the revolving edge, exceeds, we are confidently assured, anything yet achieved by rifles. The disc, which has a close-fitting covering and several other addenda to facilitate the surer aim, is set in motion by a wheel worked either by a single man, or, in the case of heavy balls, by a steam-engine. This novel catapult—which it may have struck the reader, is constructed upon the same principle of centrifugal force active in man's oldest projectile, the sling—may, it is asserted, be made to hurl from 60 to several hundred balls towards a point in a minute. The first specimen of his gun was submitted by Dr. Steinheil to the inspection of the Bavarian War-office as early as 1832. Sixteen years later he produced another and heavier machine of the same sort, throwing grape, and requiring a steam-engine to work it. In both instances the Bavarian War-office passed a favourable opinion upon the cannon, but did not think it adapted for other purposes than the defence of fortresses and ships. The secret of the invention, the transpiring, the machine appears to have been imitated in several quarters, and also got to America, where it reached the Emperor Napoleon. In Germany the Brothers Eberhardt, at Ulm, have just turned out an offensive weapon, operating, it would seem, on the same principle, but having four barrels instead of one, and the case with the French "infantry cannon." Each barrel is stated to be capable of 60 discharges in a minute. Should all this be confirmed by the experience sure to be made in more than one place, it is, perhaps not too sanguine to entertain a hope that war will become more and more rare, owing to the dreadful perfection of the instruments intended to further it."

Commerce.

PROGRESS OF FRENCH COMMERCE.—A work has been published by M. Devinck, formerly President of the Tribunal of Commerce, at Paris, containing an inquiry into the progress of commerce and manufactures in France. From this it appears that in 1851 the commercial and manufacturing situation of France was as follows:—Imports, 1,094 million francs; exports, 1,353 millions, making a total of 2,614 million francs. In 1866 the imports were 3,528 millions, and the exports 4,087 millions, or, in all, 7,615. In 1866, for the first eleven months only (the general balance not having been yet established) there is a total of about 6,500 francs, being an increase in fifteen years of nearly 300 per cent. In 1851 the number of French vessels which entered or left the French ports was 34,436. In 1866 the figures rose to 51,156, showing for maritime commerce alone a progress of about 50 per cent. In 1851 the network of railways measured 3,500 kilometers (five-eighths of a mile each), but at the end of the year 1866 it showed a length of 14,000 kilometers actually at work. The concessions form a much larger amount—more, in fact, than 21,000 kilometers. In 1851 the telegraphic service possessed 100 stations for 3,000 kilometers, and transmitted 10,000 despatches. In 1866 it was in operation for a distance of 31,500 kilometers, possessed 2,100 stations, and transmitted 2,500,000 despatches. The charge has been reduced by 70 per cent. since 1851. The number of letters carried in the earlier period was 65,000,000, whereas in 1866 it had risen to 329,000,000. The postage has been diminished on an average one-fifth, and the conveyance has become four times more rapid. In 1851 the amount of discounts at the Bank of France was 1,241 millions, whereas in 1866 it was 6,574 millions. During the same period the produce of the coal-basins has been increased twofold, and that of the manufactures in cast and wrought

tripled. The state has executed great works for improving the navigation of canals and rivers. By raising up the tolls paid to companies the tariffs have everywhere been either suppressed or lowered. In the 1851 the indirect taxes and those on consumption reached a sum of 738,242,000 frs.; in 1852, 804,334,000 frs.; and 1856, 1,282,268,000 francs. At the same time that the consumption has been so prodigiously devoted to the great profit of the Treasury, the public works have been most considerable. In fifteen years France has furnished capital, the amount of which may be set down at 20,000 millions, which has been either invested in loans contracted by different governments, employed in the establishment of railways, formed of powerful companies, or in great works of public utility, and in material improvements of every kind.

Colonies.

INTERCOLONIAL CUSTOMS DUTIES.—A Queensland paper, referring to the impediments caused to trade by the existence of border custom-houses, says:—“There ought to be no necessity for any thing of the kind between the different Australian colonies, and it should be avoided by a mutual recognition by the various governments of what is just and equitable to each other. An increase of traffic across the different borders as trade relations increase will eventually bring about the first steps towards federation in the establishment of one uniform system of customs duties, the proceeds being equitably divided between the colonies. In the meantime it is the duty of each of them to make such temporary arrangements as shall give substantial justice without interfering with the freedom of trade.”

Publications Issued.

MODERN MARINE ENGINEERING APPLIED TO PADDLE AND SCREW PROPULSION. By N. P. Burgh, Engineer. (And F. H. Spon.) This work treats of ordinary, compound, and expansive engines, adapted for paddle, screw, and twin screw propulsion; of surface and injection condensers; of expansion, equilibrium, slide and other valves; of link motion, starting gear, thrust blocks, idle wheels, screw propellers, ordinary and superheating high and low boilers, and other subjects connected with marine engineering. It contains 36 coloured plates, 259 practical illustrations, and 403 pages of letter-press, the whole being an exposition of the present practice of the following leading firms:—Messrs. J. Penn and Son, Messrs. Maudslayi, Sons, and Field, Messrs. James Watt and Co., Messrs. J. and G. Rennie, Messrs. Napier and Sons, Messrs. J. and W. Dudgeon, Messrs. Penhill and Hodgson, Messrs. Humphreys and Tennant, Mr. J. F. Spencer, and Messrs. Forrester and Co. Mr. Burgh is also author of “A Treatise on Sugar Machinery,” “Practical Illustrations of Land and Marine Engines,” “A Pocket Book of Practical Rules for Designing Land and Marine Engines, Boilers, &c.,” “The Slide Valve Practically Considered,” “The Manufacture of Sugar, and the Machinery Employed for Home and Colonial Purposes,” &c.

Notes.

POST-OFFICE ALTERATIONS.—The Postmaster-General has issued announcements of several alterations with respect to foreign mails. One is to the effect that the limit in weight of books and patterns sent to the East Indies has been raised from 3lbs. to 5lbs. Another states that, as the Peninsular and Oriental Steam Navigation

Company are about to withdraw the extra steam vessels which they have appointed experimentally to sail from Suez to Bombay simultaneously with the packets which leave Suez about the 5th and 20th of each month for Madras and Calcutta, the last extra mail from London to Bombay will be forwarded from London on the 20th May, *via* Southampton, and on the 27th May, *via* Marseilles; and thence forward, and until further notice, correspondence addressed to the East Indies will be despatched as it was despatched previous to January 20th last. It is also stated that the postal commission has been re-established between Vienna and Constantinople, by way of the Danube and the Black Sea. Advantage will be taken of a line of railway which has just been opened between Rutschuk and Varna. Mails for conveyance by this route are despatched from Vienna on Mondays and Fridays, and letters from the United Kingdom will be in time for the mail of Monday if despatched from London *via* Ostend, on the morning of the previous Saturday, and for the mail of Friday if despatched from London on the morning of the previous Wednesday. Letters from Constantinople, which the senders may desire to forward by this route, must be specially addressed “*via* Ostend. The postage will be 9d. for a letter not exceeding half-an-ounce in weight when pre-paid, and 11d. if sent unpaid.

LITERARY CONGRESS IN PARIS.—La Société des Gens de Lettres has decided to hold an international congress during the present exhibition season, in order to give literature all the advantage that may be derived from the presence of foreign writers in Paris; these will be invited to attend the meetings and debates of the society, the dates of which will shortly be published. The society considers that now that barriers are disappearing, and distances are almost effaced by mechanical means, literary questions increase in importance and interest to all the world instead of merely to the nations in which they arise. Travelling, translation, and the increasing study of foreign languages are tending to make literary productions universal property, which all are called to watch over and diffuse. Lastly, the hope is expressed that such a congress may lead to the establishment, in other countries, of societies of men of letters similar to those which render valuable service to French writers.

CONCENTRATED MILK.—The *Estafette* of Lausanne says that the business in concentrated milk at Cham, near Zoug, promises to become of importance. The method employed is thus described: the milk is placed in an apparatus where the aqueous portion is withdrawn by a kind of air pump; a certain quantity of sugar is then added, and when the milk is of the consistency of thick honey, it is placed in tin boxes and hermetically sealed. One litre of the concentrated milk is said to be equal to more than four litres of fresh milk.

A GLASS HOUSE.—A large building, five stories high, to be used as a factory, is being erected in the Rue de Tardy, at Saint Etienne, which attracts great attention. With the exception of the back wall, the whole façade is of glass; in fact, the three sides consist of iron frames supported by stone columns, and filled in with sheets of thick glass.

To Correspondents.

ERRATA.—In the last number of the *Journal*, p. 403, col. 2, last line, for “59,” read “55;” p. 404, col. 1, line 2, for “56,” read “59;” col. 2, line 18, for “400,” read “360;” p. 406, col. 2, line 58, for “74,” read “745;” at p. 406, col. 2, line 62, for “quantity,” read “quality.”

Journal of the Society of Arts.

FRIDAY, MAY 24, 1867.

Announcements by the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

MAY 29.—“On the Water Supply of the Metropolis in relation to the Conservancy of the Thames and its tributaries, and the demands of the Water Companies.” By J. BAILEY DENTON, Esq.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object, and on their recommendation, have passed the following minute:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government, to facilitate the visits of skilled artisans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed, in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of his grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with

the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

HARVESTING OF CORN IN WET WEATHER.

The Council of the Society of Arts have resolved to offer the Gold Medal of the Society, and a Prize of Fifty Guineas, for the best Essay on the Harvesting of Corn in Wet Seasons.

The first part of such essay—after noticing the various systems at present adopted in damp climates for counteracting the effects of moisture upon cut corn in the field, and for avoiding such exposure in wet seasons by peculiar harvesting processes—should furnish a practical and analytic exposition of the best available means:—

- 1st. Whereby cut corn may be protected from rain in the field.
- 2nd. Whereby standing corn may, in wet seasons, be cut and carried, for drying by artificial process.
- 3rd. Whereby corn so harvested may be dried by means of ventilation, hot air, or other methods; with suggestions for the storage both in the ear and after threshing.
- 4th. Whereby corn, sprouted, or otherwise injured, by wet, may be best treated for grinding or feeding purposes.

The whole to be supplemented by a statement of practical results, and actual cost of each system described; and authenticated estimates of any process proposed for adoption, based upon existing but incomplete experiments.

The above requisitions are given suggestively; not to bind the writer to the order or to limit the treatment of the subject, provided it be kept within the scope of practical experience and utility.

The essays must be sent in to the Secretary of the Society of Arts on or before the 1st of January, 1868.

The Council reserve the power to withhold the whole or part of the prize, in the event of no essay being, in the opinion of the judges, of sufficient merit.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed “Coutts and Co.,” and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

A meeting of the Sub-Committee on Meat was held on Wednesday, the 8th instant. Present—Mr. Clare S. Read, M.P., in the chair; Mr. Ware, Professor J. Wilson, and Mr. Ludford White.

Mr. HERMAN GEBHARDT attended at the request of the Committee, and gave evidence as follows:—

The CHAIRMAN—I believe Mr. Gebhardt you are a large salesman and commission-agent in the Metropolitan Cattle Market?—Yes.

Do you receive many cattle from abroad?—Those which are consigned to me are all from abroad—cattle and sheep too.

Can you give the Committee any idea of the number of cattle you sell per week?—It depends upon the season of the year. Formerly we did not sell so many in spring and winter, because the supply consisted principally of grass-fed beasts, which came from July up to Christmas; but of late years the extension of railways abroad, and the increased facilities of steam communication, have made a total revolution in the trade, so that now we get almost as many in winter and spring as we used to get in the summer and autumn. I will put before you a statement I took from the *Times* yesterday morning, showing that this week, to 6th of May, the importations of foreign cattle, including sheep, pigs, and calves, was 12,099 into London; whilst for the corresponding week in 1858 it was only 1,840; that is, only less than a tenth of the number. In the corresponding week of last year the number was 8,572, so that the increase in the present year has been over 4,000 head for the week. I have received on an average, between 300 and 400 beasts, and more than 2,000 sheep from abroad.

You are probably the largest foreign salesman in the market?—No: I should say there are two firms who sell as many as I do. As an individual, having no partners, I probably sell as many cattle as either of those two firms.

Has your business increased very much of late years?—Yes; in proportion to the increased numbers of cattle sent. Nine years ago there were only 1,800 head per week amongst us all; now there have been over 12,000, and my own business has increased in proportion; but I may say I had more of the 1,800 in proportion eight years ago than I have of the 1,200 now. My own business may have been doubled, while the importation has increased tenfold.

How long have you been a salesman in this market?—I have been eighteen years in this country, but before I came here I was the largest cattle dealer in Hamburg. I am a native of Hamburg, and when the tariff to England opened, I was the first of three men who commenced exporting beasts. Formerly it was the case that all the cattle were shipped from Hamburg, and they were brought there for the purpose of meeting a sale; but people opened their eyes, and they found they could do in two days what used to take a fortnight. A line of steamers was established, and the cattle were sent from various parts, by which the driving of herds long distances was saved. We still get cattle from some distant parts, but I hope they will not come any longer. I made a communication to Professor Simmonds at the Privy Council on this subject, because a question was asked in the House of Commons by Lord Dunkellin, and Lord Robert Montagu gave an answer that the late reappearance of the cattle disease was believed to have been occasioned by a cargo of white Austrian beasts. We have reason to believe that there is always more or less a rinderpest or cattle plague in some of the countries east of Hungary.

That you would call the home of the cattle plague?—Yes; I believe many salesmen here are of the same opinion as myself on that point. I think we should give the government every assistance when we apprehend there is anything wrong, because it is better to shut up part of the continental market than the whole; and if you allow cattle to come through these districts they may infect the whole of the cattle in their course, and the importation must be prohibited entirely. The great safeguard against rinderpest in this country is the very severe and stringent measures which the foreign governments adopt for their own protection. I received

a letter this week, which I translated and sent to Professor Simmonds, stating that the Prussian government, the Bavarian government, and the government of Saxony have now totally prohibited the importation of Hungarian cattle. Professor Simmonds and Professor Brown have attended the market every day, in order that the attention might be directed to any case of disease which appears there, as it would not do for me to act as a common informer against the other salesmen. I have a great suspicion that there would be 270 cattle smuggled through, and we waited for them coming in, but at this time they have not appeared. I had a letter stating it was intended to attempt to smuggle these cattle through. The result was, in Saxony, Prussia, and Bavaria they said, "We will not allow a single Hungarian bullock to come into our country." A friend of mine, who lives at Vienna, had last week 120 beasts sent to get them as far as the Bohemian frontier by railway, and there they were stopped. These were Hungarian beasts, but they had been fattening for six months in Austria, and on that representation being made to the governments of Prussia and Saxony, they were allowed to pass. On their arrival here I showed them to the officers of the Privy Council, but they had no disease. I have no doubt there will be a good many more of these beasts come; but at present there are no cattle allowed to come from those districts which are regarded as the principal seat of the rinderpest, and such as do come are sent through. It was rumoured that a Polish Jew had sent through the 270 beasts to which I have alluded; but I do not believe it, as, according to my advice, they would have been here by this time.

You think it unsafe to promote importation from this district?—I do not believe this Government has the power to prohibit them; but you are protected by the other governments. There exists great jealousy in the trade. The Berlin jobbers send their principal supply from Prussia. They are jealous about the beasts, because they lower the market. Last week the beasts were unsaleable in the market. There were no buyers for the whole lot. There has not been such a glut of cattle for years as there was last Monday, and we are over-done just now with this particular class of beasts. For fear of rinderpest the Austrian and other governments will not allow Hungarian beasts to enter the territories, and that is a great protection to this country.

To return to your own trade—you say that now days you receive a great number of these foreign cattle in the winter-time and spring. Do you attribute this entirely to the development of railway and steam communication, or do you think it is in some degree attributable to the improvements in cattle-breeding on grazing on the Continent?—I attribute it chiefly to the development of railways, because we can get beasts here now which we could not get formerly. We have regular steam communication with Sweden, and the cattle trade with that country has sprung up within the last two years. Previous to that the only communication with Sweden was by sailing-ships. There is now a line of very fast steamers, as also to the north of Denmark—Jutland. Formerly, all the cattle from those parts had to be driven to Hamburg and shipped from that port to London; now we have steamers from Denmark direct. Within the last week we had two cargoes, consisting of 200 beasts, which, two or three years ago we should not have dreamt of getting. From Spain I am in the habit of receiving every week a cargo of 100 or 150 beasts. There are large steamers now entirely employed in the cattle trade from Geestemunde, and it is the same with Portugal. Then a fresh trade has sprung up from France. It shows how the circumstances of countries alter. I remember, seven or eight years ago the French came over here to buy cattle—now we receive a large number of cattle from France; those from Normandy being remarkably beautiful animals, as good as any English beasts which are bought by the West-end butcher—

They are a sort of half-bred shorthorn, are they not?—You would not know them from the English beasts. If we could only exclude that corner—Hungary—where we always run the risk of disease, I think there is wonderful scope for the importation of foreign cattle.

Does not your observation with regard to France sending us cattle, instead of sending here to buy them, indicate that some improvement in agriculture must have taken place?—Yes. I believe in France it is so. Some years ago they were very short indeed of stock. The present facilities for sending cattle here, added to the inducement of high prices, have tended to increase the importation from that country; indeed I am told that cattle grazing in Normandy, paying freight to this country, will realise as much to the farmer as he would get by sending them to Paris and paying the duty.

Professor WILSON.—That observation has equal bearing with regard to France, Sweden, and Denmark.—It is, no doubt, the fact that cattle intended for our market are cared for and fed differently to what is the case for those designed for home consumption, because inferior beasts, they know very well, will not fetch good prices in this country, and it does not pay them to send them here. At the same time I do not think they are advanced in agriculture sufficiently to supply us to a very large extent at present with well-bred and well-fed stock; but that they are greatly improving in this respect there can be no doubt, and it is their policy to do so.

Mr. LUDFORD WHITE.—Do you not consider that the high price of meat in this country of late years has been a great incitement to the exportation of cattle from the continent?—No doubt, but there has been a great deal of money lost lately by the foreign dealers. We had high prices last year; people abroad thought we had no cattle left, and all that sort of nonsense. The cattle I am selling now were probably bought in as store stock last November, and they are sold by live weight. Cattle feeding is done on a very large scale abroad—not like the little farmers here, with 20 or 30 beasts each. If you go into the district of Magdeburg you will find 400 to 500 beasts on one estate. If you ask how much per head for them, they will tell you, "These beasts cost me so much per head alive; so and so are my terms." If you do not like the price they will wish you "good morning." Then the jobbers will go and offer an advance of so much per cent., and this year, I have no doubt, some of them will be ruined. I believe some of them gave more for the cattle they bought in last November than they could sell them for since. Last year mutton made 6s. per stone, which is now selling at 4s. 8d., or 7d. per pound instead of 9d.

The CHAIRMAN.—Then I think I am right in the assumption I started with, that the increased importation of foreign stock is, in a great measure, due to the improved agriculture of those countries?—No doubt to a great extent it may be so. I would say this—first of all we have cattle in the winter from countries from which we formerly received none, because there were no facilities for conveyance; but when people find a market open to them they naturally try to increase the quantity, and to improve the quality of their stock; and no doubt they have gone on improving their stock very fast. They imported hundreds of bulls and rams from this country for the sake of improving their breeds of stock, till the cattle-plague came amongst us; since then all importations from England to the Continent have been prohibited. One country is afraid of the other. You could not possibly send a bull or a ram to these countries now, if you paid ever so much money to do it. I have myself a fine herd of pedigree cows in this country. I have never had the disease amongst them, notwithstanding I had foreign sheep located not far from them, and on one occasion some of them broke through the hedge, and got amongst the cows. I have got these cows now, and I cannot send one of these to the Continent. The foreign breeders would improve their stock most by improving their blood.

Professor WILSON.—They are all striving for that; but it will be years, probably, before they will take any more stock from England for breeding purposes.

The CHAIRMAN.—Is it your opinion that the continental farmers are desirous of improving their stock, and the system of feeding their cattle?—No doubt about it; farming property abroad is at least double the value it was.

Mr. LUDFORD WHITE.—And you believe the supply to be illimitable?—If you go to these countries and see the amount of stock they have left, the supply may be said to be almost unlimited; because look at the extent of grazing country they have. Gentlemen travelling through Germany must have seen the vast tracts of fine meadow land, which are capable of being mowed two or three times a year for hay, and then leave fine pasturage. You do not see such meadows in Leicestershire or Nottinghamshire, only in Holland and Germany.

Professor WILSON mentioned that he was in Jutland last year, and he was assured, on the most unquestionable evidence, that they could supply this country with 40,000 cattle per annum with the greatest ease. Last year they exported 39,000 head of cattle, and they could increase that number by 10,000 a-year for almost any time to come. He had no doubt that was quite within the mark of the capabilities of that country. In addition to which, they could send us 3,000 or 4,000 tons of oil-cake annually to feed our own cattle upon.

Mr. WARE.—In what condition do the foreign cattle come to the market as compared with the English?—Generally speaking, in very good condition, because it does not pay a man to send a bad quality of stock to our market; whether an animal fetches £10 or £30, there is the same expense of conveyance, &c., and no one dreams of buying foreign cattle for store. When a middling animal is slaughtered, it is sold at a low price, and the same may be said of all cattle which have been fattened after having been worked at ploughing. They are very fat inside, but they do not make good meat.

Do they suffer much from the voyage?—That depends upon the weather and the accommodation in the steamer. I believe there has been a wonderful improvement in this respect. I was examined on this subject before the Committee of the House of Commons in connection with the Bill of the Harwich Steam Company. I believe the shorter you can make the sea passage the better it is for the animals. I give a perfectly unprejudiced opinion on this matter, as I am not connected with any railway or steam-boat company, and, as I have generally something to do with every cargo of cattle that comes to London, I may be considered a fair judge. I have found that when a cargo of cattle from Hamburg arrives at Blackwall, which is the nearest point for landing, as soon as the steamer slackens speed, to come to her moorings, the current of air into the hold is so much decreased that the animals begin to suffer greatly from the heat. In weather like this it would be a dangerous thing to slacken speed at Gravesend, but they must gradually slacken speed in coming to an anchor in the Thames. In hot weather the animals come from the lower hold in a very distressed condition, and it always is a great point to get them landed as soon as possible after their arrival. On the passage the hold is supplied with air by wind sails carried down the hatches, and as these steamers run at a speed of ten miles an hour a considerable current of wind is driven down the hold. It is of the first importance that the cattle should be removed from the steamer immediately on their arrival at Harwich, and then sent by rail, as by that means a saving of 10 or 12 hours is effected in bringing them to market.

Professor WILSON.—Have you seen the new steamers which have been put on the Baltic line from Hamburg and Denmark to Leith?—No, I have not.

Professor WILSON.—In those steamers every provision and precaution is made for the accommodation and comfort of the animals conveyed in them, and the percentage of waste which the cattle sustain is very

small indeed. The whole of the arrangements on board are of the most excellent description, and the animals are landed immediately upon their arrival.

Mr. GERHARDT—As being a large representative of the foreign cattle trade, I considered it my duty to state my views on this subject before the Committee of the House of Commons, and I have expressed my opinion that the sea passage should be as short as possible, and that the animals should be released from the vessel as soon as possible after arrival. The principal trade in cattle lies in the hands of the General Steam Navigation Company; but they have only one wharf at Blackwall, which is not suitable for a trade like this, as there is not half room enough, and there is no proper accommodation for the cattle on their being landed there. They have sometimes to remain there all night if the steamer arrives too late for the cattle to be sent away that day. You do not know the mischief that is done to the animals. When the cattle are landed and sent away immediately after their arrival, they are generally in such a condition you would hardly think they had been 48 hours at sea.

Mr. LUDFORD WHITE—Which do you consider affects the cattle most prejudicially, the journey by sea or by railway?—That by sea, undoubtedly. On the railway they have plenty of air and sufficient room. The overcrowding of the cattle on the railway is provided against. They only carry a certain number of animals in one truck. I have had hundreds of cattle consigned to me, which came up from Harwich by the Great Eastern line, and I do not allow them to be unfairly loaded, but whilst they are in the hold of the vessel they are beyond my control. The regulation as to the number of cattle which a steamer should be licensed to carry would hardly meet the case, inasmuch as a steamer which could accommodate 200 Jutland cattle could not stow 150 of the larger breed of animals which come from Magdeburg and other parts of Germany. Facilities of traffic are best promoted by competition in the trade—railways against steamers, and steamers against railways—and the dealers will always find out which is the best way of sending the cattle.

The CHAIRMAN.—I will ask you, supposing there should be a market established, say at Thames Haven, with suitable slaughter-houses, for the slaughtering of all the foreign cattle at that or some other spot near, so that these animals might be excluded from the Metropolitan Live Cattle Market altogether, do you think such an arrangement would tend materially to reduce the supply sent to this country?—A very great deal; in fact it could not be done. If it were tried I am sure it would have to be given up. Imagine a day like this—[referring to the heat]. We are only now at the commencement of summer. You slaughter the animals at Thames Haven, and by the time you get the meat into the salesmen's shops at the market how much do you think would be fit for consumption? It might answer better in winter, but even then it would place restrictions upon the trade which would be most undesirable. Practically it could not be done, I am quite convinced. You must understand that the meat trade in London is not all carried on by the carcase butchers. A large number of beasts are killed by the retail men, from which they derive a considerable portion of their profits in the sale of the offal. It is calculated that the retail man is able to make 15s. or £1 more of the offal of a bullock than the carcase butcher can do, who has to sell it to wholesale dealers in the same way to be retailed by them. In summer time the small retail butchers would not kill a bullock or a sheep till late at night, so as to have it fresh for his customers in the morning. Imagine such a supply of foreign stock as we had last Monday, when there were 2,430 beasts and 8,666 sheep in the market; how is it possible any man should know what quantity he should kill? Besides, if I were a retail butcher, and I were in my shop, I should know I wanted a bullock to be killed for the supply of my cus-

tomers. I could have it killed at the time I wanted it, to suit my trade. But if I am a carcase butcher, if I kill 20 beasts and only 10 are wanted, I have 10 left on my hands; if, on the other hand, I only kill 20, and 40 are wanted, I am 20 short in the supply I require. How can you possibly regulate the supply in that way?

The CHAIRMAN suggested that the telegraph might be employed for the purpose. The distance to Thames Haven was not great, and there was direct communication with London.

Mr. GERHARDT—Yes; but the retail butchers would not go in the evening, and say to the carcase butcher, "I shall want a carcase to-morrow morning." The consequence would be some parts of London would be partly without meat, and some parts would have three times more than was wanted. The foreign cattle constituted at least one-half of our supply at present, and it was in much larger proportion than that during the cattle plague.

The CHAIRMAN—You suggest that if the system of slaughtering the foreign cattle at Thames Haven were adopted London would be sometimes deprived of half its proper supply of meat, and at other times the market would be glutted. Have you ever found that to be the case at present?—We find sometimes the prices are fabulous, and sometimes they are equally low, because the supply has been in excess of the requirements. The place of slaughtering which you suggest might be available to some extent in the winter time; but in summer it would be quite impossible to use it. It would be the very thing, in my opinion, to restrict the importation of foreign cattle.

The CHAIRMAN—I did not suggest that the system should be limited to one place; besides Thames Haven, you might do it at Southampton and Leith?—It might be done in places of 10,000 to 20,000 inhabitants, but to attempt to feed three millions of people in this artificial way could never be done, nor do I see any good that could arise from it. You bring the beasts into London, but none are allowed to go out again. You can make yourselves safe against the cattle plague, first, by not allowing any cattle to come in from the countries which have got it.

The CHAIRMAN—But you cannot always tell where the cattle comes from?—The governments abroad assure you, because they will not let them come into their country. They have had the plague in Holland, and we have not had a bullock from there. You can stop them at the wharf; and if they are brought into market they can be stopped there.

The CHAIRMAN remarked, unless something of this sort were done, there was no probability of getting rid of the cattle-plague in London.—My second proposition is that every animal should be inspected on its arrival here; and let every animal be killed within a certain time, which is the regulation at the present time. With regard to the disease that has lately broken out at Limehouse in a cowshed, I do not find that it can be traced to any foreign beasts.

The CHAIRMAN—This Committee has been appointed for the purpose of inquiring into the means by which the supply of meat to this country can be increased, and the price cheapened; and you are of opinion that there is immense scope on the Continent for increasing the supply; and that as the facilities of transit are enhanced the development of the foreign cattle trade will continue to progress?—Yes; no doubt; if you do not clog the trade with unnecessary restrictions. You have a still better remedy against the cattle plague. There might be a separate market for foreign live cattle, away from the other; they need not mix with the English beasts; and as they left the market only to be killed, they would not take the disease into the country. I think you have the remedy entirely in your own hands, in the way I have suggested. Farmers in the country can send their cattle to other markets in the country without sending them to London at all:

ough the Metropolitan Market is always considered to be the best.

THE CHAIRMAN—The Metropolitan Market is, no doubt, the great market for live cattle, and in course of time you might develop another permanent market; at present there is no other market at which you can sell the quantity of cattle you can sell here?—No; at present the farmers in the country have the opportunity of sending their cattle to the provincial markets without their coming to London at all. Those northward of London have the Hitchin market.

If a person required foreign cattle, why should he not go down to Thames Haven to buy them?—You must make a complete revolution in the trade; because the retail men, who sell their two or three beasts per week, could be brought into the position of mere meat-dealers, and it would involve a loss to them of 15s. or £1 in the matter of the offal. In the case of the contracts for the supply of meat for stores for troops and the navy at Deptford, the contractor is obliged to dispose of his fat wholesale; but the retail man makes a considerable profit by the retail of the offal; and, as I have said, do not know how this slaughtering at the place of de-carication could be carried on at all in the hot weather of summer. The great secret is, in summer time, to kill the meat as late as possible, so as to give it time to "set" before it is taken to market. I have seen a great deal of meat that has come from Thames Haven stopped as unfit for food, and if it had not have been stopped no respectable butcher would have bought it. The meat sent from the country in quarters is packed in cloths and hampers; but it would be impossible to do that with the quantity required for the metropolitan market.

But it comes in that way from Aberdeen?—That is early all sent by private butchers. It does not come from any abattoirs. With regard to the danger of cattle lague, if you bring the cattle to Harwich to be killed here, you might as well bring them to London. The best thing the Government did, in my opinion, was to drive every cow out of London, for the cowsheds are the hotbeds of disease. For my own part, I would not allow a single cowshed in London, as the system of keeping and feeding is altogether bad, and the danger of the spread of cattle disease is greatly increased by that means. I consider it would be a great advantage that cows should be kept in the country, inasmuch as if the animals are properly fed, the whole of their food is produced in the agricultural districts; and roots, as well as hay and grass, where they are grown, must all be brought up from the country. I think there ought to be legislation on the subject of the London cowsheds. If there were no cows kept in London for milking purposes, even if the plague was brought into London by foreign cattle, it would do no mischief, because there would be nothing to catch it, whether the cattle were brought from Harwich or Thames Haven.

MR. LUDWIG WHITE—Would it not increase the price of milk in London to abolish all the cowsheds?—No; the cows would be kept near London, and on the spot where the food is produced. The principal portion of the London supply of milk comes from the country now.

In reply to further inquiries, Mr. Gebhardt expressed his opinion that the dead meat trade from the continent might be developed in the winter. All the objections he had stated applied principally to the hot period of the year; but he had seen beef, even in winter, in such condition that one would not like to eat it, and when wetted with sea water it very soon became in a bad state; and large quantities had been condemned at Blackwall. The value of the offal of a bullock in good condition, including the hide, was from £3 5s. to £3 10s., and the depreciation upon that according to the circumstances of having a retail market or not for the edible portions, generally purchased by the poorer classes, was from 15s. to £1. The tongues were sold wholesale at 8s. 6d. each, but if he wanted to buy one he must give 10s. for it. He believed no foreign beef was bought by

the principal West-end butchers, except sometimes the very best quality of French beasts, and they must be very choice for the West-end men to buy them. The foreign meat principally goes to supply contracts for the army and navy, and a great many are disposed of to the carcase and retail butchers of Whitechapel and other portions of the east of London. At last Monday's market the best price was 4s. 10d. a stone, and some was sold at 4s.; the average price of the market was 4s. 6d. per stone. The cost of transit of cattle from Hamburg is about £2 per head; from Berlin £3, and from Vienna £4 to £5 per head. The concession to the consignee is about 6s. 6d. per head, which includes the market charges. It was impossible for him to say at what cheaper rate the foreign producers could raise their stock as compared with the English farmer; and unless prices kept up, money would be lost upon store stock bought at high prices last autumn. Many graziers had sold their stock when fat at almost the same price which they gave for them as stores; and this remark equally applied to sheep.

CANTOR LECTURES.

"ON POTTERY AND PORCELAIN." By W. CHAFFERS, Esq.

LECTURE VII.—MONDAY, MAY 20.

ENGLISH PORCELAIN.

The subject of Mr. Chaffers' concluding lecture was English porcelain. He began by observing that the invention of the manufacture of porcelain in this country was much earlier than had been generally supposed; for a patent was taken out by John Dwight, of Fulham, in 1671, while that of Chicaqueau, of St. Cloud, in France, was not granted until 1702, nearly thirty years afterwards. The first discovery in that country was accorded to Louis Poterat, of Rouen, who obtained letters patent in 1673, but the ware never succeeded, and only a very imperfect description of china was produced; Dwight's porcelain was therefore made two years previously, and the words of his patent are these:—"For the mystery of transparent earthenware commonly known by the name of porcelane or China." The fact is corroborated by Dr. Plot, in his "History of Oxfordshire," written in 1677, who says—"He" (Dwight) "hath found ways to make an earth white and transparent as porcellane, and not distinguishable from it by the eye, or by experiments, that have been purposely made to try wherein they disagree." The principal test of porcelain being its transparency, there can be no doubt about the nature of the ware here spoken of. A specimen of his porcelain, of about 1735, has recently been discovered; it is a bust of George II., of small life-size, in porcelain, which, from the peculiar modelling, and the similarity to Dwight's busts in stoneware, leaves no doubt of its origin. It is in the possession of Mr. Reynolds. The manufactory at Stratford-le-Bow was established about 1730. Thomas Frye, an eminent painter, appears to have been instrumental in bringing the china to that perfection for which it was celebrated. In 1753 the works passed into the hands of Messrs. Crowther and Weatherby. In an interesting document, accompanying a Bow china bowl which was presented to the British Museum by the painter himself, we are told that they employed 300 persons; about 90 painters and 200 turners, &c., all under one roof. In 1775 the Bow works were sold to Mr. Duesbury, and all the moulds and implements transferred to Derby. [Several specimens of Bow and Chelsea were exhibited.] The celebrated manufactory at Chelsea was established about the same time as Bow, and the early productions are frequently mistaken the one for the other; but, fortunately, the finer pieces are usually marked with an anchor in red or gold. The period of its greatest excellence was from 1760 to 1765. It has been thought that Venetian workmen were first engaged here, from the great similarity of the two wares both in painting and gilding, added to which the mark

upon both is an anchor. This manufactory was set on foot by Mons. Spremont, a Frenchman, and he acquired a great fortune. The beautiful vases in the French style of grobleu and morone, with beautiful paintings, are well known, and are at the present day much appreciated, the prices they command being as high as are paid for the Sévres porcelain. These works were also bought by Mr. Duesbury, of Derby, in 1769, who continued them at Chelsea until 1784. The china made by him was called Derby Chelsea, and is known by the mark of a D, crossed by an anchor. Although the Derby works originated as early as 1750, it does not appear that any china of a high character was produced, but principally services and small chimney ornaments; and it was not until 1769, on the purchase of the Chelsea works, and a few years after of those at Bow, that they rose to any importance. In fact, with the best workmen and painters of those great establishments, and all the moulds and models from them, the Derby manufactory may be considered as the Bow and Chelsea manufactories continued in another locality. Some beautiful examples of porcelain in the Chinese style were produced, and they seem also to have copied their marks, as well as their style of decoration; but their ordinary trade mark was at first a D crossed by an anchor, called Derby Chelsea, and after Royal patronage was accorded, in 1780, it was changed to a D surmounted by a crown—this was called Crown Derby, and was used by the successor, Mr. Bloor, down to 1830. The works ceased in 1848. The next porcelain manufactory of importance was Worcester, established chiefly through the exertions of Dr. Wall, who formed a company in 1751. The services made here were held in much estimation, and although produced at a cheaper rate than Bow or Chelsea china, were better for use, and not so subject to crack with hot water. An important means of decorating porcelain was introduced here in 1759, by transferring impressions from engraved copper plates on to the surface of the ware. It was adopted almost simultaneously with Liverpool, the invention being claimed by both, and specimens of these productions are found bearing the names of Sadler and Green, of Liverpool, and Richard Holdship, of Worcester, dated in the same year. Bat-printing succeeded the printing from copper plates on paper; the impression being taken from a copper plate by a piece of glue (called a glue bat), which received the pattern on its surface in oil, and being pressed on to the surface of the ware, the design was transferred; it was then dusted with colour and baked. The porcelain made from 1760 to 1780 was of a superior quality, and the colours used on decorative pieces approached very closely to those of Chelsea. In 1783 the manufactory was purchased by Mr. Flight, afterwards Flight and Barr, and many clever artists were engaged; it remained with them and their successors until 1840, when the two principal manufactories of Worcester, Messrs. Flight and Barr, and the Messrs. Chamberlain, were amalgamated, the concern taking the name of the latter. Chamberlain's works were established in 1786, and acquired a great reputation, being especially patronised by the Prince Regent, for whom they made a service which cost £4,000. Another full service for the East India Company at Madras was supplied at a still higher price. The taste for gilding and bright colours caused this great increase of price, for it appears that nearly £1,000 per annum was paid by the firm for gold alone. Caughley, near Broseley, Shropshire, was celebrated for porcelain. Mr. Turner, an engraver, from Worcester porcelain manufactory, made great advances, especially in services for the table; he invented a beautiful blue, which was printed on the ware in Chinese designs. The well-known "willow pattern" was produced here in 1780, which, even at the present day, is in great demand; this was the first blue printed table service made in England. The porcelain manufactory of Nantgarw was established by a Mr. Billingsley, in 1813. He had some time before produced his beautiful transparent ware at Pinxton, but its expensive character prevented it from

becoming successful, and it was abandoned; he, however, revived it at Nantgarw, and it was so much admired that Mr. Dillwyn, of Swansea, made arrangements with Billingsley to superintend the production of it there also. Nearly all the ware made at Nantgarw was purchased in the white by Mortlock, a china-seller of London, and decorated in the metropolis. The favourite patterns at both the above-named places were pink roses heightened with gold. Mr. Rose, of Coalport, was a celebrated potter, and he established himself there about 1780. He was not, however, contented with such limited operations, but as the Caughley, the Swansea, and the Nantgarw works were successively relinquished by their owners, he became the purchaser, and incorporated them with his own, retaining Billingsley as director of his manufactory. The patterns known as the "worm sprig," the "Tournay sprig," the old "willow pattern," and the "blue dragon," remained staple articles. His decorative porcelain he marked "Coalbrookdale," which was another branch of his Coalport works. William Cookworthy, the inventor of hard porcelain, commenced his experiments as early as 1758, but it was not until 1768 that he considered it fully developed, and in that year, in conjunction with Lord Camelford, he took out a patent and commenced operations at Plymouth. The materials employed were called growan stone and growan clay, which answered to the ingredients of the Chinese porcelain, *kaolin* and *petuntse*. The difficulties found in proportioning them properly, so as to give exactly the necessary degree of vitrification and no more, and other niceties with regard to the manipulation, discouraged them in their proceeding in the concern, and, after expending on it between two and three thousand pounds, they sold their interest in the patent to Mr. Champion, of Bristol. The works were, however, carried on for nearly six years, and a considerable amount of ware was produced. Cookworthy engaged the services of a clever French artist, who produced the articles modelled in the form of shells and rock work, which became great favourites for the table. In 1774, the patent was sold and transferred to Mr. Richard Champion, of Bristol. He made some beautiful ware, but the great outlay prevented it being remunerative, and in three or four years he was compelled to give up the manufacture, and sold the patent to a company of Staffordshire potters. Various other porcelain manufactories were described; among these the New Hall China Works at Shelton, the first of the kind in Staffordshire. They had purchased Champion's patent, intending to make hard porcelain, but in a short time this was abandoned, and they made the usual English soft paste china, in which a great proportion of bone dust was mixed. The important china works at Stoke-upon-Trent originated with Josiah Spode in 1794. Great improvements were made by him and his sons in the composition of porcelain, and they introduced a fine and durable material called iron stone china, which was largely exported to France, to the great injury of the French trade. The Prince of Wales visited the works in 1806, and he appointed Spode potter to his Royal Highness. About 1827, Messrs. Copeland and Garrett succeeded, the works being still carried on by Mr. Alderman Copeland, and the choice pieces which emanate from this establishment vie with the famed *petite tendre* of old Sèvres, while the jewels which glitter upon it remind us of the lines in Shakespeare about gilding refined gold or painting the lily. On others the exquisite paintings are veritable works of art, and the beautiful bisque figures are unapproachable. Mr. Thomas Minton established works at Stoke-upon-Trent in 1790. He made porcelain in the Worcester style and realised a handsome fortune. He died in 1837, and was succeeded by his son, Mr. Herbert Minton, who attained great celebrity as a potter, and brought the ware generally to great perfection. He revived the manufacture of encaustic tiles, and by employing the most expert artists, the most skilful chemists, and sparing no expense in his

numerous experiments to improve the colours, the body of the ware, and the decorations, he stood unrivalled in his art. His successors, Messrs. Michael Dainty, Hollins and Colin Minton Campbell, have pursued the same course, and with untiring energy and zeal seconded all his efforts. Mr. Chaffers remarked that England has indeed reason to be proud of the rival potters, who have furnished forth their specimens of porcelain to the Paris Exhibition of 1867. Only two have exhibited, but the names of Minton and Copeland have added lustre to the English potters' art, and have borne away the palm of victory. Mr. Chaffers had on the table some fine specimens of the beautiful china produced at Bockingham by the Messrs. Brameld, from the year 1820, under the protection of Earl Fitzwilliam, the owner of the estate at Swinton. The china was of a superior description, and the painting and decoration generally of the highest order. The manufactory was discontinued in 1840. The important manufactory of porcelain at Lowestoft was established about 1756, and it is remarkable that the recollection of its existence, and the productions which emanated from it, should have been lost sight of and gradually died away, although it was in active work for nearly fifty years, and only ceased in 1802. But although this is the case at a distance from the locality, it is well remembered by the older inhabitants of Lowestoft, and the houses in the vicinity are teeming with its china. In fact, it is to be found all over England, but is usually, for want of a truer name, called Oriental, being a sort of hybrid ware, which nobody who knew what real Chinese porcelain is could for a moment mistake. The painting on the ware, too, is undoubtedly English, and the very touches of the artists can be identified. Its greatest prosperity was from 1770 to 1800. The question about hard paste being made at Lowestoft is placed beyond dispute; it was probably introduced about 1775 after Champion's failure. There are several persons now living who can testify to the fact that no Oriental porcelain ever came into the factory to be decorated; yet this is the opinion of many who have not duly considered the matter, and who imagine that what is now called Lowestoft was actually Oriental china, painted only at that place. Mr. Chaffers referred those of his hearers who wished to judge for themselves to a large collection of Lowestoft china, which he had obtained from the gentry of the vicinity, and which was now exhibited in the South Kensington Museum.

The CHAIRMAN said this lecture closed the Cantor Lectures for the present Session; and he felt sure that he expressed the sentiments of all who had heard Mr. Chaffers' course, when he said they were deeply indebted to that gentleman for the large amount of information he had brought before them. The lectures had been made additionally interesting by the very numerous and valuable specimens which Mr. Chaffers had been enabled to place before his audience, illustrating the various manufactures referred to in the lectures. In the name of the audience, he begged to tender their thanks to Mr. Chaffers.

THE ROYAL ALBERT HALL OF ARTS AND SCIENCES.

The first stone of this hall was laid by Her Majesty the Queen, on Monday morning last, on the site, north of the gardens of the Royal Horticultural Society at Kensington. Her Majesty, accompanied by the members of the Royal Family, arrived at half-past eleven, and was received by His Royal Highness the Prince of Wales, the Chairman of the Provisional Committee, and the Duke of Edinburgh. The Prince of Wales read the following address:—

"May it please your Majesty,—

"The report which, as President of the Provisional Committee of the Hall of Arts and Sciences, I have the honour to lay before your Majesty will be found to con-

tain a brief outline of the origin and progress of the undertaking to the present time.

"It is not necessary for me to remind your Majesty that the building of which you are graciously pleased to lay the first stone to-day is one of the results of the Exhibition of 1851, and that it forms a prominent feature in the scheme contemplated by my dear father for perpetuating the success of that Exhibition by providing a common centre of union for the various departments of science and art.

"I cannot doubt that to your Majesty the events of this day, with their manifold associations, must be full of mournful interest. For myself, I need not say that, sharing these feelings, it is also with gratification that I find myself co-operating in the endeavour to give effect to a plan which had commended itself to the judgment of my father.

"Your Majesty's presence to-day will be the best encouragement to us to persevere in the work, and render it in all respects worthy of the object for which it is designed."

To this Her Majesty made the following reply:—

"I thank you for your affectionate and dutiful address. It has been with a struggle that I have nerved myself to a compliance with the wish that I should take part in this day's ceremony; but I have been sustained by the thought that I should assist by my presence in promoting the accomplishment of his great designs to whose memory the gratitude and affection of the country are now rearing a noble monument, which I trust may yet look down on such a centre of institutions for the promotion of art and science as it was his fond hope to establish here. It is my wish that this Hall should bear his name to whom it have owed its existence, and be called 'The Royal Albert Hall of Arts and Sciences.'"

The report referred to by his Royal Highness was then handed to her Majesty. It is in these terms:—

"May it please your Majesty,—We, the provisional committee appointed by the promoters of the Central Hall of Arts and Sciences, and now acting under your Majesty's Royal Charter of the 8th April, 1867, humbly beg leave to submit to your Majesty the following report of the circumstances which led to the present undertaking, and of the steps we have taken in virtue of the powers entrusted to us.

"After the close of the Great Exhibition of 1851 representations were made to your Majesty's Commissioners for that Exhibition from chambers of commerce, learned societies, and other bodies interested in science or the arts, of the want that was felt throughout the country of a central institution in London for the promotion of scientific and artistic knowledge as applicable to productive industry. Your Majesty's Commissioners, being impressed with these representations, announced in their second report to your Majesty that they had devoted the surplus funds of the Great Exhibition to the purchase of an estate at South Kensington with a view of providing a common centre of union for the various departments of science and art connected with industrial education.

"After the purchase of this estate, numerous plans for effecting the contemplated object were prepared, under the immediate direction of your Majesty's lamented Consort, the president of the Royal Commission, in all of which a central hall formed a prominent and essential feature.

"The untimely death of the illustrious Prince led, in conjunction with other causes, to the suspension of the steps necessary for carrying into effect the comprehensive scheme contemplated by his Royal Highness and your Majesty's Commissioners.

"An advance, however, has been made towards its realisation, by the establishment of the South Kensington Museum, and of the Royal Horticultural Society, on the estate purchased by the Commissioners. A large portion

of the estate has also been made available for purposes connected with the objects of the purchase, by allowing its occupation by the buildings of the International Exhibition of 1862; and a part of those buildings now contain the second of the series of Exhibitions of National Portraits which it is proposed to hold there, besides affording space for a large collection of models of naval architecture.

"It will be in the recollection of your Majesty that the committee named by your Majesty to advise your Majesty on the subject of a national memorial to the Prince Consort, recommended the erection of a hall on this spot as a fitting portion of that memorial, and the Commissioners expressed their willingness to give effect to that recommendation by the grant of a site.

"Designs for a personal monument and a hall of art and science were accordingly submitted to your Majesty. It was found, however, that the available funds would not be sufficient for the execution of the double object, and your Majesty, acting under the advice of the committee, determined to appropriate the whole sum to the one object of the personal monument in Hyde-park now in the course of construction, opposite the site on which the hall is to be erected.

"The intention of constructing the hall, however, was not abandoned; and in the year 1865 many of those who had taken a deep interest in the Great Exhibition of 1851, and in the success of the further plans arising out of it, formed themselves into a committee to consider the readiest mode of obtaining the means of erecting this hall. The Royal commissioners lent their willing co-operation, promising the free grant of a site valued at £60,000, and further agreeing, on certain conditions, to advance the sum of £50,000 towards the cost of the hall.

"On the 6th July of that year a general meeting of the persons interested in the undertaking was held at Marlborough-house, at which we were appointed a provisional committee, with full powers to adopt such measures as might appear to us best calculated to carry the proposed undertaking into effect, his Royal Highness the Prince of Wales accepting the office of president. Your Majesty's gracious patronage was at the same time vouchsafed to the undertaking.

"Acting upon the powers thus conferred upon us, we took steps for obtaining subscriptions, and in the course of last summer the sum subscribed had reached the amount of £112,000. The monetary panic which occurred about that time made it then expedient, in our opinion, to suspend our efforts in this direction.

"The other preliminary steps necessary for the prosecution of the work were, however, actively proceeded with. A design sketched for the hall by the lamented Captain Fowke, was worked out by Lieut.-Colonel Scott, of the Royal Engineers, assisted by the advice of a scientific committee of architects and others, and was finally approved by us.

"At the same time an offer was made by Messrs. Lucas, the eminent builders, and accepted by us, which provided the remaining funds and secured the completion of the building within the original estimate of £200,000.

"The excavation of the foundation was at once commenced, and we felt ourselves in a position to announce to the public the beginning of the work, and to make the application to your Majesty, which met with your Majesty's gracious acquiescence, that your Majesty would be pleased to lay the first stone of the proposed hall in person.

"We beg humbly to submit to your Majesty plans showing both the external elevation and interior arrangement and decoration of the hall.

"We are convinced that by the erection of this central hall we are supplying a great public want, and acting strictly in accordance with the enlightened views of your Majesty's Illustrious Consort, and of the commission of which he was the head.

"It is our grateful duty, in conclusion, to return to your Majesty our humble thanks for the marks of your

Royal favour at all times extended to us in connection with this undertaking, for the grant of your Majesty's Royal Charter of Incorporation, for your Majesty's liberal subscription towards the funds of the hall, and for your auspicious presence on this occasion. We would venture to hope that a continuance of your Majesty's support may be vouchsafed to us in the further prosecution of a plan destined, as we confidently trust to prove of lasting benefit to the interests of science, art, and to add to the enjoyment and instruction of myriads of numbers of your Majesty's subjects."

Her Majesty then left the Throne, and went to lay the foundation stone, which was of red polished granite, and bore, in gold letters, the following inscriptions:—

"This stone was laid
by her Most Gracious Majesty
QUEEN VICTORIA,
May 20th, 1867."

The various coins of the realm, and an aged scroll, containing a description of the undertaking, had been handed to her Majesty by the Earl of Derby. Lord Granville presented the vase in which they were enclosed. The Queen placed the coins and the scroll in the vase, and closed it. By her Majesty's orders Lieut.-Colonel Scott, R.E., director of the works, laid the stone in the cavity. Mr. Lucas, the builder, then placed on the Queen a gold trowel, having first placed a mortar on the four corners of the lower stone. The Queen, after spreading the mortar, gave the word, and the corner stone began to descend into its place, and a flourish of trumpets and a Royal salute. The Queen, with a plummet and line, tested the accuracy of the block's adjustment, and, striking it with an iron hammer, declared it "well and truly fixed," and loud cheering. The Archbishop of Canterbury then offered up a short prayer, and the band and chorus of the Royal Italian Opera performed a composition by the Prince Consort, entitled *L'Invocazione all'Armonia*.

The Hall of which Her Majesty has laid the foundation-stone is to be available for the following objects:—Congresses, both national and international; purposes of science and art; performances of music; distributions of prizes by public bodies; conservation of the promotion of science and art; agricultural, historical, cultural, and industrial exhibitions; and displays of pictures and sculpture.

The central portion of the Hall will be occupied by an arena of 100 ft. long and 65 ft. wide, measured on the diameters of the oval. It is intended to use this arena for an audience during orchestral performances, when it will contain 800 or 900 persons, to be admitted by payment or by tickets granted for the occasion. At other times it will be a promenade, or be used for exhibitions of flowers, sculpture, or the industrial arts. Above the arena will rise the amphitheatre, extending over four-fifths of the oval in a gradually increasing curve of ascent. Each step or bench will be three ft. wide, and the whole will be seated with comfort in 360 chairs. The freeholds of these sittings are to be sold to subscribers for £100 each sitting. The sittings themselves will be transferable by sale or otherwise, or the right of occupying them may be sold either for a period or any particular occasion. In all, there will be about 1,720 of these amphitheatre sittings, and of these 360 can be converted if necessary into 360 sittings. The remaining part of the oval will be occupied by sittings for an orchestra of 1,000 performers, and by a very fine organ, to be built by Mr. William the maker of the organ for St. George's Hall, Liverpool. Above the amphitheatre again will rise two tiers of boxes. Those in the lower tier are each to contain ten persons, and are to be sold for £1,000 each; those in the upper tier will contain five persons each, and are to be sold at £500 the box. The boxes will be, like the sittings, transferable, and each of them will be provided with a small room behind it. There will be 43 in the principal tier.

and 86 in the upper. The provisional committee have proceeded on the principle of retaining full powers for the shareholders over those portions of the Hall which can be used for exhibitions or for other purposes connected with the objects of the undertaking. No seats will be sold which in any way interfere with the various purposes for which the hall is intended. Above the boxes will be a corridor, 21 ft. wide, which is to be fitted with movable seating. This arrangement will allow it to be used for a sitting audience, a promenade, or exhibition space. It will give space for seating 2,700 persons. The wall of the corridor may be considered to bound the hall proper, and from wall to wall on the longer diameter of the oval it will measure 230 ft., and on the shorter, 180 ft., which enormous stretch is all to be covered in with a roof in one span, resting on piers, between which the spectator in the hall will see the architectural features of a top-lighted picture gallery and promenade running completely round the hall. This gallery would also be available for a seated audience on great musical festivals, and will conveniently accommodate 1,000 persons. The total number, therefore, that could be conveniently seated in the building will be 8,000, including the orchestra, and if of these the provisional committee have to sell only 2,000, as the statement put forth by them implies, there will be no less than 6,000 sittings for *entrepreneurs* using the hall. From the top of the piers which separate the upper galleries from the main body of the hall the ceiling will rise in an elliptical curve to the great central skylight, both ceiling and skylight being suspended from immense wrought-iron arched ribs or girders. The total height from the floor of the arena to the skylight will be 135 feet. Commencing to work downwards from the upper gallery there will be immediately below it numerous offices, rooms for societies using the hall, and refreshment and promenade rooms, and extending from the general contour of the hall there are to be over the entrances on the one side a lecture theatre, and on the other a small concert room. Below this floor will be the crush rooms, which are to give admittance to the corridors surrounding the boxes, and also to the galleries. Behind the orchestra, at the ground level, and also on a level with the lower tier of boxes, will be long refreshment and promenade rooms. The basement will be occupied with the kitchen, stores, &c., so arranged that the lifts from the kitchen will pass through all the refreshment rooms on the three floors above.

The arena is to contain 800 to 1,000 people. There are to be four staircases on the south-east and south-west side, and two on the north side, or a staircase for every 166 persons. There will be also six staircases to the box tiers, besides an entrance from the conservatory of the Royal Horticultural Society, where there will be two flights of steps, making in all eight staircases for 860 people, or a staircase for every 108 people. To the lower gallery, which will be occupied by persons admitted for comparatively small payment, there are six staircases, 6ft. 6in. wide, for 2,700 persons. The upper gallery is to be provided only with two staircases 6ft. 6in. wide, but space is to be left for additional staircases in case of their being required. The amphitheatre sittings will be entered from the level of the ground in Kensington-road. The means of egress are to be very ample. Counting two entrances to the corridor of the Horticultural Society, from the arena level there are to be no less than 29 exit doors, which assuming the number of persons capable of being collected in the Hall, will be one for every 275 persons. For the refreshment department there will be provision made for dining, if necessary, 1,000 persons; but the kitchen will admit of any extension required, and the hall will give the power of dining in the arena and on the two gallery floors no less than 2,000 persons. It is contemplated that during great choral festivals the conservatory of the Royal Horticultural Society will be lighted and thrown open to visitors to the Hall as a promenade.

PARIS EXHIBITION.

The weather has been as bad here as in London, only two fine days or so during the last fortnight, but the public has fallen into the habit of going to the Exhibition, and, as the weather permits of little promenading in the park and garden, the building itself is at least as well filled as it was during the precociously hot weather which ushered in the month of May. The means of transit from, if not to, the exhibition are still far below the requirements of the public; the trains on the railway are unaccountably few in number, only one per hour during the greater part of the day; the steam-boats are too small, the omnibuses too few, and as to cabs, nothing will induce the drivers to go to the Champ de Mars for a fare when they find them with the greatest ease in the heart of Paris. As usual, in Paris, individual enterprise is not to be depended upon; and although the authorities have had more than one meeting of cab-proprietors, nothing has yet arisen out of them to supply the public want. The only extraordinary effort that has been made is the conversion of a number of very rude vans, with tarpaulin covers, into public conveyances, but they are a mere drop in the ocean of tired pedestrians wearily trying to make their way to the town, where they may recruit their famished bodies at prices more moderate than those of the Exhibition, which are tolerably high, though perhaps not extravagantly so. The great international restaurant has a large number of visitors, but while its position, in the furthest part of the park, is no obstacle in the case of hale men, it is so as regards many other persons, especially after the fatigues of the Exhibition.

For the Exhibition itself, that is to say, the contents of the building, every day brings its importance more and more to light. The juries have completed their examination, and although nothing is yet officially known concerning the awards, it is not too early to point out a few of the novelties, improvements, and examples of excellence, which must have attracted the attention of the juries, as well as of other observant persons. The general progress of science, art, and taste is of course a subject of interest to all the world; but charity begins at home, and it would be mere hypocrisy to pretend that the figure which Great Britain makes in the Exhibition is not uppermost in the minds of Englishmen.

We have already said something on this head in connection with the fine arts and the "Histoire de Travail," or retrospective gallery. It is time now to take a general glance at the industrial portion of the Exhibition, and, for more reasons than one, the great machinery court or gallery of the useful arts claims precedence. And first, as regards machinery in motion, it may be stated that the arrangements for the supply of motive power are on a liberal scale, and Great Britain is better off than her neighbours in one of her specialties, namely steam. Messrs. Galloways, aided by two other boilers, those of Messrs. Heywood and Tyler, and Howard, supply all that is required to keep anything moving that is intended to move during the whole number of hours that the Exhibition is open, while in the other departments an evident economy of power is necessary. When the great machinery court has been carefully examined, it will hardly be said that the importance of the English collection of machinery is unworthy of the nation. The limits of the *Journal* will only permit of a summary notice of the most striking objects, and of short notes even respecting them. At the head of the machinery stand the steam-cranes, which must not be overlooked; they did great service; they enabled the British commission to outstrip all their rivals in getting their portion of this enormous court early into order, and they await the closing day to render like service again. There was, as far as we know, no steam-crane on the ground before those from England arrived, and certainly no other nation made such extensive use of them. Close to them stands a collection of other machinery and apparatus,

very different, indeed, in aspect, but having the same useful object, namely, the rapid despatch of business; these are the models contributed by her Majesty's Post-office, the railway sorting carriages, the ingenious apparatus for picking-up and dropping letter-bags on the lines, and the tables and other arrangements for sorting and stamping the letters. In this department we stand yet completely unrivalled, and the Post-office models are a source of constant admiration. We understand that Prussia has some arrangement for the taking-up of bags *en route*, but we believe that no other country has yet adopted a plan so long in operation, though in its present complete form, in our own country.

Close to the Post-office models stands a case which contains illustrations of another of England's triumphs, during the twelve years that have elapsed since a universal exhibition was held in Paris, namely, the models of the machinery used in the process of making Bessemer steel, which is now adopted more or less all over Europe.

Amongst the first model machines that the visitor encounters in the same part of the gallery are three for mining and tunnelling; one of these is the "iron man," or coal-getting machine of Messrs. Carrett, Marshall, and Co., of Leeds, moved by water power under high pressure, and which works by scoops affixed to a prolonged piston arm; and the machine of Messrs. Jones and Levis for the same process, but in a very different manner, the action being that of an immense pick, with a radial sweep of four or five feet, and worked either horizontally or perpendicularly by a compressed air engine, at the rate of 200 strokes a minute.

The third machine referred to is Capt. Beaumont's rock boring machine and tunnelling machine, also moved by a compressed air engine. This machine is known to engineers, having been used for some time at the Vartrey waterworks at Bolton le Moors, but others may be interested to know that it consists of a large wheel, or chuck, armed with 50 powerful chisels, or, as they are technically called, "jumpers," which have a circular and reciprocating motion, caused by the alternate advance and retreat of the piston and axis of the chuck, while a still larger jumper or drill, with an X cutting face, works a hole in the centre. It is said that with about 15-horse power, this machine will cut a circular groove in hard rock to the depth of a foot; when the groove is cut to the depth of 2ft. or 2ft. 6in., the machine is drawn back, powder is placed in the central hole, and the isolated circular pieces of rock blown to pieces.

Near this spot are several steam engines of new or improved construction which must not be overlooked. They include a horizontal engine by Messrs. Donkin, a powerful one by Galloway, an Allen engine by Whitworth, a Corliss engine by Hick, of Bolton, two improved portable engines by Ransome and Sims, and the steam-hawling engine of Baron de Mesnil, made by Fowler.

In this section of the court may be seen in action models of one of the most important tools that has ever been designed, namely, Ramsbottom's patent duplex horizontal steam hammer, manufactured by Messrs. Thwaites and Carbutt, of Bradford. There are only seven of these hammers yet at work, one of 30 tons at Crewe, and six of ten tons in other places, so that this must be regarded as a positively new form of tool. The same firm shows one of the finest pieces of iron workmanship in the exhibition, a wrought-iron stand for a vertical hammer, with balanced piston, for working Bessemer steel.

The working model of a steam pile-driving engine, and a full-sized engine of the same kind, but different model, in the park must not be left unnoticed.

The wood-working machines are numerous in the exhibition; and while the lighter kind differ but little from those of our own friends in this country, where the famous ribbon saw was, we believe, invented, or at any rate first exhibited in 1855, the heavier machines show an immense improvement in the arrangement of

their parts and the solidity of their construction: the development of this class of machine tools is a thing which marks the interval between the two Paris Exhibitions.

Since the first Great Exhibition our neighbours have made great strides in the construction of iron-working machine tools; but an inspection of those in the present exhibition will not injure the reputation of Great Britain for the production of these most important of all engines except the steam-engine. The show is very large, and almost without exception there is evidence everywhere of improvement—in principle, in detail, and in workmanship; where all is so good it is almost impossible to select one name, but there is in the collection of Messrs. Sharp, Stewart, and Co., a connecting rod complete finished by machines of this kind, which may well be cited as an example of the perfection of the best kind of tool-making machines. For perfection of workmanship again we must quote the taps and dies and the templates exhibited by Whitworth and Co., and Sharp, Stewart, and Co., not as anything new, but certainly as unsurpassed.

The spinning and weaving machinery in the British side is certainly second to none in the exhibition.

Amongst scientific apparatus must be mentioned an improved revolving light of the Trinity-house, and within the machinery court, and the magneto-electric light of Professor Holmes, and his steam engine worked by condensed air, in the park. The machines used for the magneto-electric light are placed for inspection in a small building at the foot of the scaffolding upon which the light is supported. The fog-horn, which now and then sends its loud but musical notes across the park from the French lighthouse, where it has been hospitably housed; we understand that the French Government has adopted this valuable nautical safeguard.

Besides, further portions of the machinery court are devoted to apparatus of various kinds, and numerous accessories; and amongst the objects which deserve special notice are the lap-welded and other tubes, coils, and hollow ware of various kinds; railways and other springs, buffers, &c., of which there is a great show by nearly all the great firms.

The show of improved blacklead crucibles is striking, and those of the Patent Crucible Company are particularly so, as having, as certificates show, being adopted by nearly all the mints in Europe, including that of Paris; such crucibles used to serve but one hour, they bear the fierce heat of the gold furnace fifteen or sixteen times.

In telegraphic apparatus England makes a very good show, but the name of Wheatstone is a host in itself; and Messrs. Siemens have some apparatus of novelties in the way of hollow conical iron pipes for over-ground telegraphs and insulations. But in railway signalling apparatus England certainly stands first. The beautiful model of Messrs. Saxby and Farmer's system of signals in use at the Cannon-street station, exhibited by the maker, has attracted great attention, and the arrangement has been adopted recently for the Belgian lines.

Stoneware and other sanitary apparatus is also largely and admirably represented; while means of preservation of life are represented by a noble lifeboat, three steam and other fire-engines, and a fire-escape, which create great curiosity. The steam fire-engines have been tried several times, and on one occasion Merryweather's fire engine threw a stream of water over the top of the French lighthouse, which is 150ft. high.

In the *Journal* of the 10th instant was given the list of medals awarded in the class of painting; those of other classes of the Fine Art group have now been announced. In sculpture Mr. Wyon obtains a third-class medal; in architecture, a grand medal is awarded to Mr. Waterhouse; a medal of the first-class to the late Captain Powke; a second-class medal to Mr. Lynn; and one of the third-class to Mr. Barry.

In engraving and lithography, England obtains no distinction of any class. Considering that the English engravers exhibiting number nearly fifty, and considering also the high esteem that British engraving enjoys in France, the non-appearance of the name of any English engraver or lithographer in the list of awards is strange.

The analysis of the fine art rewards gives the following result:—

	France. Prizes.	Other countries. Prizes.
Painting.....	32	35
Sculpture	23	13
Engraving, &c.....	8	5
Architecture	12	11

So that, according to the opinion of the international juries, painting is relatively her weakest, and sculpture her strongest, art point.

Colonies.

COMMUNICATION WITH AUSTRALIA.—A conference has been held at Melbourne, consisting of the representatives of the different colonies. It was decided to maintain mail communication with Europe by the three routes, namely, Suez, Panama, and Torres Straits. The preliminary steps to permanently carry out this arrangement will be to memorialize the Imperial authorities to terminate the existing contract with the Peninsular and Oriental Company, and at the same time to ask the Home Government to grant a moiety to be contributed in agreed-to proportions by the different colonies. It is expected that the Torres Straits route will be of great advantage to Queensland, in indirectly helping to open up the northern portions of that vast colony. By the new arrangement on this route it is intended that the mail steamers should sail direct from Singapore, without calling at Batavia, as doing so would involve a loss of two days. Queensland undertakes to light and buoy the straits, and ultimately to extend the telegraph wires to Cape York. When this is done—and it is expected that two years will see its accomplishment—Australia will be placed within twelve days' telegraphic communication with England. Of course the different intercolonial governments will have to endorse the doings of the delegates in Melbourne before any decided action can be taken, but where the advantages are believed to be so obvious it is not expected that any difficulty or delay will occur on this score. It may be added that the sum of £400,000 was agreed upon as a sufficient subsidy to carry out the recommendations of the delegates.

Correspondence.

MR. FOTHERGILL COOKE'S PAPER.—SIR,—I beg to correct a slight error in the report of what I said in the discussion on Mr. Cooke's paper, read on Wednesday the 15th inst. I did not speak of "the power of the saws to cut deeper than their semi-diameter," which would be an impossibility; what I intended to convey was that the property in Mr. Cooke's saw, of not decreasing in semi-diameter by wear, was a great advantage. Also, both at pages 424 and 425, the word "Hand saws" should have been printed "Sand saws."—I am, &c.,

R. J. LECKY.

The Collings Engineering Works,
199, Westminster-bridge-road, May 20th, 1867.

THE FOOD COMMITTEE.—SIR,—A gentleman who gave evidence before the Food Committee on the 17th April, states that the cattle in Australia are in best condition for slaughtering during the hot weather, when it is difficult to cure the meat; and that if the cattle were killed in the winter, the meat would be in such a thin and lean

condition that it would not be acceptable in this country. I think want of local knowledge has led this witness a little astray. During a residence of upwards of 20 years in Queensland and New South Wales, engaged the whole of that time in the active management of large cattle stations, I have always found cattle to be in their best condition in May, June, July, and August, these being the four coolest months of the year. The reason is obvious; the grass is in the best fattening condition from January to June, and of course the cattle are in their prime as the grass begins to go off; in other words, after they have derived all the benefit they can from the luxuriant pasture. As to meat preserved in canisters "producing dysentery from the effect of certain gases generated in the canisters," I suspect the fact is, that if meat on the verge of decomposition is packed in canisters, it will undoubtedly produce dysentery, and so it would if it had been eaten without being packed in canisters. If the meat is perfectly fresh when it is hermetically sealed, there need be no fear of dysentery, or any "hurtful gases being generated." At the Australian Meat Company's preserving establishment the beef is hermetically sealed, and the whole operation concluded within twenty-four hours from the time the bullock is slaughtered.—I am, &c., THE MANAGER OF THE AUSTRALIAN MEAT COMPANY.
137, Houndsditch, London.

Journal of the Society of Arts.

FRIDAY, MAY 31, 1867.

Announcements by the Council.

It is with deep regret that the Council have to record the death of their Chairman, Sir THOMAS PHILLIPS, Q.C., on Sunday last, the 26th inst.

In consequence of this event, the Society's Ordinary Meeting, fixed for Wednesday evening last, was postponed by order of the Council.

ORDINARY MEETINGS.

Wednesday Evenings at Eight o'Clock:—

JUNE 5.—“On the Water Supply of the Metropolis in relation to the Conservancy of the Thames and its tributaries, and the demands of the Water Companies.” By J. BAILEY DENTON, Esq.

ANNUAL CONFERENCE.

The Sixteenth Annual Conference between the Council and the Representatives of the Institutions in Union and Local Boards will be held on Wednesday, the 19th June, at Twelve o'clock, noon. The Right Hon. HENRY AUSTIN BRUCE, M.P., will preside.

The Council will lay before the Conference the Secretary's Report of the Proceedings of the Union for the past year, and the Results of the Examinations, as well as the Programme of Examinations for 1868.

Secretaries of Institutions and Local Boards are requested to send, as soon as possible, the names of the Representatives appointed to attend the Conference, and early notice should be given of any subjects which Institutions or Local Boards may desire their Representatives to introduce to the notice of the Conference.

Secretaries of Institutions are requested to forward *at once* by book post, copies of the last Annual Reports of their Institutions.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent

study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object, and on their recommendation, have passed the following minute:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government, to facilitate the visits of skilled artisans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed, in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

HIS ROYAL HIGHNESS THE PRINCE OF WALES, President of the Society, has presented a donation of Thirty Guineas.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed “Countts and Co.,” and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

FINAL EXAMINATION, 1867.

PRIZES AND CERTIFICATES AWARDED TO CANDIDATES.

PRIZES.

HIS ROYAL HIGHNESS THE PRINCE CONSORT'S PRIZE OF TWENTY-FIVE GUINEAS TO 951—William Meadows, aged 19, of the City of London College, clerk, who, in this and the three preceding years, has obtained the following First-class Certificates:—

1864. Chemistry—First-class Certificate, with First Prize.
 „ Animal Physiology—First-class Certificate, with First Prize.
 „ Geometry—First-class Certificate, with First Prize.
 1865. Book-keeping—First-class Certificate.
 1866. Navigation and Nautical Astronomy—First-class Certificate, with First Prize.
 „ Principles of Mechanics—First-class Certificate, with First Prize.
 „ Algebra—First-class Certificate.
 1867. Arithmetic—First-class Certificate, with Second Prize.
 „ Domestic Economy—First-class Certificate, with First Prize.
 „ English Literature—First-class Certificate, with First Prize.
 „ Mensuration—First-class Certificate, with First Prize.

Arithmetic ...	1st Prize	£5	To No. 1278—Richard Henry Barrett, 18, Portsmouth Dockyard School engineer student
	2nd Prize	3	„ 951—William Meadows, 19, City of London College, clerk <i>No Prize for Females awarded†</i>
Book-keeping	1st Prize	5	„ 828—John Butler, 26, Leeds Church Institute, railway clerk
	2nd Prize	3	„ 850—Robert Archer Furbank, 22, Leeds Mechanics' Institute savings' bank clerk <i>No Prize for Females awarded.†</i>
Algebra	1st Prize	5	„ 434—Edmund Felix Mondy, 21, Deptford Local Board, shipwright
	2nd Prize	3	„ 127—Daniel Welwood, 17, Belfast Academy, clerk
Geometry ...	1st Prize	5	„ 118—William Whitford, 22, Belfast Academy, flaxdresser <i>No Second Prize awarded*</i>
	1st Prize	5	„ 951—William Meadows, 19, City of London College, clerk
Mensuration..	2nd Prize	3	„ 384—John Henry Morrison, 21, Chatham, &c., Mechanic's Institution, shipwright
	1st Prize	5	„ 1268—Thomas Edwards, 18, Pembroke Dock Mechanics' Institution, shipwright (apprentice) <i>No Second Prize awarded*</i>
Conic Sections	1st Prize	5	„ 1286—Henry Palmer, 21, Portsmouth Local Board, shipwright
	2nd Prize	3	„ 434—Edmund Felix Mondy, 21, Deptford Local Board, shipwright
Navigation & Nautical Astronomy	<i>No Prizes awarded†</i>
Principles of Mechanics...	1st Prize	5	„ 1278—Richard Henry Barrett, 18, Portsmouth Dockyard School engineer student
	2nd Prize	3	„ 464—Alfred Morecom, 18, Devonport Mechanics' Institute, naval engineer student
Practical Mechanics	1st Prize	5	„ 461—Francis Ford, 19, Devonport Mechanics' Institute, engineer student
	2nd Prize	3	„ 1578—William H. Stanier, 17, Wolverhampton Ath., railway clerk
Electricity & Magnetism	<i>No Prizes awarded†</i>
Light & Heat	1st Prize	5	„ 973—William Vaughan, 26, City of London College, clerk <i>No Second Prize awarded*</i>
	1st Prize	5	„ 720—William Henry Wood, 18, Halifax Working Men's College, clerk
Chemistry.....	2nd Prize	3	„ 719—James William Davis, 23, Halifax Working Men's College, blue dyer
	<i>No Prizes awarded†</i>
Mining and Metallurgy..	1st Prize	5	„ 1347—Robert Creaser Kingston, 20, Richmond Parochial Library and Reading Room, gardener <i>No Second Prize awarded*</i>
	1st Prize	5	„ 1347—Robert Creaser Kingston, 20, Richmond Parochial Library and Reading Room, gardener
Floriculture...	2nd Prize	3	„ 274—William Pritchard Roberts, 27, Bromley Literary Institute, gardener

* No other First-class Certificates were given in these subjects, or the Candidates were disqualified for receiving Prizes.

† No First-class Certificates were awarded in any of these subjects.

‡ No Female Candidate qualified to receive Prizes obtained a First-class Certificate in any of these subjects.

- 777—Fillingham, Charles, 18, Hull Young People's Inst., clerk—Bkpg. (3d)
- 219—Firth, George, 18, Bradford M.I., warehouseman—Arith. (3d)
- 1049—Fisher, Henry, 22, Royal Polyt. Inst., clerk—Dom. Econ. (1st); Anim. Phys. (2d); Elect. and Magn. (2d)
- 800—Fisk, Harry W., 17, Ipswich W. M. Coll., attorney's clerk—Bkpg. (1st)
- 797—Fitzpatrick, William, 19, Ipswich W. M. Coll., railway clerk—Arith. (3d)
- 1006—Flegg, Robert, 16, London M.I., clerk—Arith. (3d); Geog. (2d)
- 827—Fleming, Thomas H., 16, Leeds M.I., brushmaker—Arith. (3d); Eng. Hist. (3d); Geog. (3d)
- 811—Floyd, William, 16, King's Lynn Ath., law clerk—Arith. (1st)
- 1507—Fogg, Frederick, 19, Stockport M.I., mechanic—Eng. Hist. (3d)
- 1637—Folkes, Oswald, 19, St. Thomas' Sch., Woolwich, wheeler—Geom. Dwg. (3d)
- 659—Forbes, Daniel W., 19, Glasgow M.I., engineer—Prac. Mech. (3d)
- 1631—Ford, Charles C., 17, St. Thomas' Sch., Woolwich—Geom. Dwg. (3d)
- 431—Ford, Francis, 19, Devonport M.I., engineer student—Arith. (1st); Prac. Mech. (1st), with 1st prize
- 624—Forrest, Thomas H., 21, Carlton-place (Glasgow) Secular Sch.—Prac. Mech. (3d)
- 686—Forster, George T., 19, Guisborough M.I., cabinet maker—Arith. (2d)
- 373—Forsyth, John, 17, Carlisle W. Men's Inst., railway clerk—Arith. (1st); Geog. (2d)
- 1298—Foster, Richard, 17, Preston M.I., warehouse boy—Arith. (3d)
- 1276—Foster, William T., 17, Plymouth Wesleyan Inst., carpenter—Eng. Hist. (3d)
- 365—Fox, John, 18, Bury Ath., fitter—Geom. Dwg. (2d)
- 234—Francis, Edward, 21, Bristol Trade Sch., certificated teacher—Chem. (3d)

- 47—Fraser, George, 20, Glasgow M.I., clerk—Bkpg. (2d)
 07—Fraser, Alexander, 16, Watt Sch. of Arts, Edinburgh, optician—Arith. (2d)
 33—Freestone, R. H., 16, Bristol Trade Sch., chemist's apprentice—Chem. (3d)
 152—Freeth, Henry, 23, Messrs. Chance's Library, glass painter—Free-hd. Dwg. (3d)
 47—Fry, Howard, 21, S.E.Ry. M.I., Ashford, engineer—Pract. Mech. (3d); Princ. Mech. (3d)
 850—Furbank, Robert A., 23, Leeds M.I., savings-bank clerk—Bkpg. (1st), with 2nd prize
 979—Furmage, Francois D., 21, London M.I., solicitor's clerk—Eng. Hist. (3d)
 608—Furniss, Thomas S., 17, Greenwich Lit. Inst., turner and fitter—Geom. Dwg. (3d)
 1330—Fyson, George, 16, Lambeth Evg. Classes, engineer apprentice—Arith. (3d)
 1026—Gale, Thomas William, 20, Royal Polyt. Inst., dentist—Chemistry (1st)
 231—Gallop, James, 18, Bristol Trade School, clerk—Chemistry (2d)
 38—Garaway, Thomas C., 21, S.E.Ry. M.I., Ashford, railway clerk—Arith. (2d)
 1615—Gardner, Charles R., 19, Sci. Sch. Royal Arsenal, Woolwich—Geom. Dwg. (1st); Anim. Phys. (3d)
 804—Garrett, George A., 22, Ipswich W. M. Coll., messenger—Bkpg. (3d)
 1077—Garstang, James John, 16, Royal Polyt. Inst., surveyor's clerk—French (3d)
 1620—Garthwaite, Robert G., 19, St. Thomas's School, Woolwich, carpenter and builder—Geom. Dwg. (2d)
 724—Gaukroger, James, 17, Halifax W. M. Coll., clerk—Arith. (1st)
 298—Gaze, Edward H. J., 19, Burrage-road Schools, Plumstead, engineer—Geom. Dwg. (3d)
 1487—Gee, Henry, 21, Staleybridge M.I., power-loom weaver—Bkpg. (3d)
 1156—Gentles, Adam, 20, Manchester M.I., railway carriage builder—Geom. Dwg. (3d)
 477—Gibbons, John, 28, Droyladen Educ. Inst., joiner—Geom. Dwg. (3d)
 1672—Gibson, Charles, 17, Belfast People's Lit. Inst., clerk—Bkpg. (3d)
 1085—Gifford, Augustus C., 16, Royal Polyt. Inst., clerk—Arith. (2d)
 1363—Gilbert, Henry E., 22, Rugby Inst., solicitor's clerk—Freehand Dwg. (1st), with 2d prize
 141—Giles, Frederick C., 16, Birm. and Midl. Inst., clerk—Arith. (3d)
 39—Giles, William T., 20, S.E.Ry. M.I., Ashford, lampmaker—Arith. (3d)
 1259—Gill, James, 24, Paisley Artiz. Inst., shawl pattern designer—Music (1st)
 546—Gillespie, John, 19, Pop. Evg. Classes, And. Univ., Glasgow, engineer—Arith. (2d); Pract. Mech. (2d); Mensur. (2d)
 870—Gladman, John, 18, Lichfield W.M. Assoc., staff sergeant—Music (2d)
 704—Glasby, Charles, 18, Halifax W. M. Coll., warehouseman—Bkpg. (2d)
 1581—Golby, Thomas, 19, Wolverhampton Ath., clerk—Arith. (2d); Bkpg. (2d)
 848—Goodall, Hamilton, 18, Leeds M.I., mechanic—Alg. (1st); Geom. (3d)
 462—Goodyear, Thomas H., 20, Devonport M.I., engineer student—Alg. (1st)
 1198—Gorbutt, John, 23, Oldham Temp. Sem., store-keeper—Arith. (3d)
 338—Gough, John, 17, Burrage-road Schs., Plumstead, engineer student—Geom. Dwg. (3d)
 175—Goulding, Ebenezer, 17, Bolton M.I., clerk—Geom. Dwg. (2d)
 607—Graham, David P., 21, Glasgow Ath., book-keeper Bkpg. (2d)
 1065—Graham, Joseph, F., 16, St. Stephens' (Westm.), Evg. Sch., clerk—Arith. (1st); Eng. Hist. (2d); Alg. (3d); Geom. (3d)
 610—Graham, Robert, 20, Glasgow Ath., wholesale newsagent—French (1st)
 1810—Grant, David, 20, Preston Inst., architectural draughtsman—Free-hd. Dwg. (1st)
 284—Gray, Alexander, 22, Burnley M.I., weaver—Bkpg. (3d)
 547—Gray, James, 23, Pop. Evg. Classes, And. Univ., Glasgow, clerk—Arith. (2d)
 937—Gray, Walter, 20, City of Lond. Coll., clerk—Arith. (3d)
 142—Green, Edmund, 21, Birm. and Mid. Inst., clerk—French (3d)
 271—Green, Henry E., 16, Bristol Trade Sch., clerk—Geom. Dwg. (2d)
 143—Green, John R., 25, Birm. and Mid. Inst., tool-maker, Geom. (3d)
 1008—Greenfield, William, 20, Lond. M.I., short-hand clerk—Arith. (3d)
 1588—Greenhill, Henry H., 17, Science School, Royal Arsenal, Woolwich, engineer apprentice—Geom. Dwg. (3d)
 295—Greenway, Charles M., 19, Burnley M.I., chemist—Chem. (3d)
 1688—Greenwood, Holmes, 19, Accrington M.I., warehouseman—Arith. (2d); Alg. (3d)
 62—Greenwood, James, 16, Bacup M.I., weaver—Arith. (3d); Geog. (3d)
 1129—Greenwood, William H., 21, Manchester M.I., engineer—Light and Heat (2d); Pract. Mech. (2d); Princ. Mech. (2d)
 1381—Gretton, John J., 19, Salford W.M. Coll., clerk—Arith. (2d); Geog. (3d)
 1270—Griffiths, Henry, 25, Pembroke Dock M. I., shipwright—Mensur. (3d)

- 56—Sutcliffe, George W., 18, Bacup M.I., weaver—Arith. (1st)
- 856—Sutcliffe, John W., 19, Leeds Y. M. Chris. Assoc., clerk—Bkpg. (1st)
- 77—Sutcliffe, Mary, 16, Bacup M.I., sewing machinist—Dom. Econ. (1st)
- 1084—Sutherland, John, 39, St. Stephen's (Westminster) Evg. School, police sergeant—Arith. (2d); Geog. (2d)
- 508—Sutherland, John, 17, Watt School of Arts, Edinburgh, draper—Arith. (3d)
- 167—Sutton, Samuel, 18, Bollington Useful Know. Soc., warehouseman—Arith. (1st)
- 845—Swinger, William, 27, Burrage-road Schools, Plumstead, draughtsman—Geom. Dwg. (1st)
- 347—Swanson, William, 18, Burrage-road Schools, Plumstead, turner—Geom. Dwg. (2d)
- 1023—Symons, James S., 30, London M.I., clerk—French (3d); Botany (3d)
- 164—Tabb, Lewis H., 18, Bodmin Lit. Inst., draper—Elect. and Mag. (3d)
- 245—Tabrett, Henry C., 17, Bristol Trade School, fitter—Geom. Dwg. (1st)
- 246—Tabrett, John W., 16, Bristol Trade School, carriage body maker—Geom. Dwg. (3d)
- 229—Tanner, Henry W. L., 16, Bristol Trade School—Chem. (2d)
- 1068—Tapp, George W., 18, St. Stephen's (Westminster) Evg. School—Bkpg. (2d)
- 478—Tapp, Miles, 19, Devonport M.I., apprentice joiner—Arith. (3d)
- 81—Tart, John B., 27, Bilston Inst., grocer's assistant—Arith. (3d); Bkpg. (3d)
- 74—Tattersall, Ann, 19, Bacup M.I., winder—Dom. Econ. (3d)
- 258—Tavener, Joseph, 19, Bristol Trade School, warehouseman—Chemistry (1st)
- 518—Taylor, David, 24, Freetown W. Men's Inst., Glossop, clerk—Bkpg. (1st)
- 1164—Taylor, Enoch, 21, Moseley M.I., cotton-piecer—Bkpg. (3d)
- 1114—Taylor, James, 18, Manchester M.I., clerk—Eng. Lit. (1st)
- 1227—Taylor, James, 18, Oldham Lyceum, mechanic—Arith. (2d); Pract. Mech. (2d); Princ. Mech. (3d)
- 467—Taylor, John A., 18, Devonport M.I., grocer—Anim. Phys. (2d)
- 1492—Taylor, Samuel, 16, Stockport M.I., book-keeper—Arith. (2d)
- 1125—Taylor, William, 19, Manchester M.I., clerk—Bkpg. (2d)
- 1170—Taylor, William, 19, Moseley M.I., warehouseman—Bkpg. (3d)
- 1149—Teggin, Edward, 16, Manchester M.I., fitter—Arith. (1st)
- 660—Thistle, Robert, 19, Glasgow M.I., clerk—Bkpg. (2d)
- 662—Thom, Andrew H., 17, Glasgow M.I., pupil teacher—Arith. (1st); Alg. (2d)
- 1066—Thomas, Charles J., 16, Roy. Polyt. Inst., clerk—Bkpg. (3d)
- 1303—Thomas, John, 16, Preston M.I., factory operative—Freehd. Dwg. (2d)
- 1413—Thomas, William, 18, Salford W.M. Coll., clerk—Arith. (3d)
- 1075—Thomas, William H., 25, Roy. Polyt. Inst., clerk—French (2d)
- 379—Thomlinson, John H., 16, Carlisle M.I.—Arith. (1st); Geom. (3d)
- 425—Thomlinson, Thomas D., 20, Crewe M.I., engine-fitter—Arith. (3d); Pract. Mech. (3d); Mens. (3d)
- 1411—Thompson, John, 20, Salford W.M. Coll.—Arith. (2d); Bkpg. (1st)
- 1185—Thomson, Catherine B., 17, New Swindon M.I. milliner and dressmaker—Dom. Econ. (1st)
- 1351—Thomson, Frederick, 22, Richmond Parochial Lib.—Florist (3d); Fruit and Veget. Cult. (2d)
- 648—Thomson, Joseph, 19, Glasgow M.I., shipwright (apprentice)—Arith. (2d)
- 578—Thomson, William, 17, Pop. Evg. Classes, And. Univ., Glasgow, clerk—Chem. (2d); Anim. Phys. (3d)
- 430—Thornley, Joseph, 17, Dean Mills Inst., piecer—Arith. (3d)
- 1172—Thornley, Richard, 17, New Mills Inst., book-keeper—Arith. (3d)
- 357—Thornton, Thomas, 21, Bury Ath., joiner—Geom. Dwg. (2d)
- 1488—Thorpe, William T., 22, Staleybridge M.I., warehouseman—Arith. (3d); Bkpg. (3d)
- 855—Tiffany, John B., 23, Leeds Y. M. Chris. Assoc., tobacco manufacturer—Arith. (1st); Mens. (2d); Eng. Hist. (3d)
- 1100—Tinker, Thomas J., 16, Manchester M.I., clerk—Arith. (1st); Bkpg. (1st)
- 352—Todd, William, 20, Lee's M.I., woollen manufacturer—French (3d)
- 32—Tomlinson, George, 17, Aldershot Local Board, clerk—Arith. (2d); Geog. (2d)
- 971—Tompkins, Amos, 22, City of London Coll., clerk—German (2d)
- 310—Topple, Alfred W., 18, Burrage-road Schools, iron turner—Geom. Dwg. (2d)
- 656—Torrance, John, 23, Glasgow M.I., grocer's assistant—Eng. Lit. (3d)
- 689—Torrance, John H., 18, Glasgow Ath., clerk—French (3d)

- 972—Trekell, C. Munro, 17, City of Lond. Coll., clerk—Arith. (3d)
- 468—Treleaven, Joseph T., 22, Devonport M.I., shipwright—Geom. Dwg. (1st); Mensur. (2d)
- 803—Trent, Henry C., 19, Ipswich W.M.C., carrier—Arith. (2d)
- 513—Tritton, John D., 18, Faversham Inst., block-maker (apprentice)—Arith. (2d); Eng. Hist. (2d); Geog. (2d)
- 1444—Trobridge, George, 16, Messrs. Chance's Schools, junior clerk—Arith. (2d); Free-hd. Dwg. (2d); Geog. (3d)
- 590—Turnbull, Alexander J., 21, Glasgow Ath., civil engineer—French (3d)
- 1182—Turnbull, George, 17, New Swindon M.I., apprentice—Arith. (3d)
- 1331—Turner, Albert, 26, Lambeth Evg. Classes, clerk—Arith. (2d); Eng. Hist. (3d); Geog. (3d)
- 1485—Turner, Joseph, 32, Staleybridge M.I., joiner—Geom. Dwg. (1st)
- 781—Turner, Margaret, 28, Hyde M.I., weaver—Dom. Econ. (3d)
- 1450—Turner, Samuel, 16, Messrs. Chance's Evg. School scorer—Arith. (3d)
- 1305—Tyson, James, jun., 17, Preston M.I., plasterer—Free-hand Dwg. (2d)
- 1355—Underwood, William, 16, Rugby Inst., railway clerk—Arith. (2d)
- 973—Vaughan, William, 26, City of Lond. Coll., clerk—Light and Heat (1st) with 1st prize; Prac. Mech. (2d)
- 512—Veitch, John, 17, Faversham Inst., teacher—Arith. (3d)
- 780—Venour, Alfred, 20, Handsworth W.M. Club, ex-pupil teacher—Eng. Hist. (3d)

- 297—Wilkinson, William C., 23, Boreley M.I., temporary letter carrier—Arith. (1st); Bkpg. (3d)
- 1543—Willatt, Sarah Jane, 20, Walsall Ch. Inst., Free-hand Dwg. (3d)
- 878—Williams, George G., 16, Liverpool Inst., clerk—Arith. (2d); Alg. (3d)

- 8—William*, John, 17, Birm. and Midl. Inst., pupil teacher—Arith. (2d)
 9—William*, John, 17, Wolverhampton Ath., whitewash—Alg. (3d)
 9—Williams, William H., 23, Southampton Ath., carpenter—Music (2d)
 9—Williamson, Jonathan, 21, Liverpool Inst., engineer—Mensur. (3d)
 10—Williamson, John, 27, Pop. Evg. Classes, And. Univ., Glasgow, wood carver—Bot. (3d)
 7—Willmott, George, 20, City of London Coll., telegraph operator—Arith. (1st); Bkpg. (1st)
 7—Willmott, Robert, 23, New Swindon M.I., engine fitter—Arith. (1st)
 17—Wilson, Edwin, 28, Scarborough M.I., hosier—Arith. (1st)
 16—Wilson, James K., 19, Watt Sch. of Arts, Edinburgh, clerk—Arith. (3d)
 10—Wilson, John, 18, Paisley Artizans' Ins., engineer (apprentice)—Arith. (2d)
 31—Wilson, John, 28, Pop. Evg. Classes, And. Univ., Glasgow, teacher—Anim. Phys. (3d)
 10—Wilson, Joseph, 17, Halifax W.M.C., bookseller—Arith. (1st); Eng. Lit. (2d)
 99—Wilson, Robert, 23, Glasgow Ath., clerk—Logic, &c. (2d)
 65—Wilson, Robert, 16, Glasgow M.I., stationers' apprentice—Bkpg. (3d)
 82—Wilson, Robert A., 20, Pop. Evg. Classes, And. Univ., Glasgow, clerk—Anim. Phys. (3d)
 15—Wilson, Thomas, 22, Halifax W.M. Coll., carpet weaver—Bkpg. (3d)
 150—Wilson, William John, 24, Royal Polyt. Inst., engineers' clerk—Anim. Phys. (1st), with 1st prize; Dom. Econ. (1st), with 2d prize
 136—Wingfield, Henry E., 17, Burrage-road Schools, Plumstead, engineer student—Geom. Dwg. (2d)
 130—Wittmann, Sidney A., 19, Royal Polyt. Inst., merchant—Germ. (2d); Italian (2d); French (3d)
 312—Wolsey, William E., 18, King's Lynn Ath., attorney's clerk—Arith. (1st)
 140—Womersley, Frederick W., 27, Hastings M.I., upholsterer—Bkpg. (2d); Alg. (2d)
 557—Wood, Alexander, 18, Glasgow M.I., clerk—French (3d)
 824—Wood, Edwin, 18, Leeds Ch. Inst., railway clerk—Bkpg. (1st)
 720—Wood, William H., 18, Halifax W.M. Coll., clerk—Chem. (1st), with 1st prize
 718—Woodhead, David, 21, Halifax W.M. Coll., oil-cloth maker—Chem. (2d)
 1376—Woodhead, Joseph, 21, St. Thomas's Ch. Inst. (St. Helen's), assistant teacher—Arith. (3d); Geog. (3d)
 45—Woodworth, William R., 16, S.E.Ry. Mech. Inst., railway clerk—Arith. (1st)
 447—Workman, Charles H., 16, Smethwick Loc. Board, glass painter—Arith. (3d); Free-hand Dwg. (3d)
 622—Worrall, William, 26, St. Thomas's School, Woolwich, writer—Geom. Dwg. (3d)
 471—Wotton, George G., 23, Devonport M.I., attorney's clerk—Arith. (1st)
 1477—Wren, Henry B., 19, Southampton Ath., clerk—Bkpg. (3d)
 978—Wright, Frederick, 18, City of Lond. Coll., clerk—Bkpg. (2d)
 1628—Wright, Henry E., 22, St. Thomas' Sch., Woolwich, schoolmaster—Geom. Dwg. (2d)
 1408—Wright, John, 16, Salford W.M. Coll., hooker—Arith. (1st)
 1122—Wright, John, 26, Manchester M.I., traveller—Bkpg. (1st)
 1229—Wrigley, William, 21, Oldham Sci. Sch., warehouseman—Geom. Dwg. (3d)
 1275—Wroe, James, 27, Swinton M.I., warehouseman—Music (3d)

- 640—Yorson, William, 21, Glasgow Inst., bookbinder—Free-hd. Dwg. (3d)
 1582—Young, Hannah E., 28, Wolverhampton Ath., private schoolmistress—Eng. Hist. (3d)
 645—Young, James, 17, Glasgow M.I., apprentice—Arith. (1st)
 598—Young, Sydney W., 21, Glasgow Ath., commercial clerk—Eng. Hist. (1st); Eng. Lit. (1st) with 2d prize; Logic, &c. (2d)
 583—Young, William, 16, Pop. Evg. Classes, And. Univ., Glasgow, clerk—Bkpg. (3d)

Instances of copying at the Examinations held under the superintendence of the Local Board of the Science School, Belfast, having been detected and reported by two of the Society's Examiners, all the candidates implicated have been excluded from receiving certificates.

Proceedings of the Society.

CONVERSAZIONE.

A Conversazione took place at the South Kensington Museum on Thursday evening, the 23rd inst., when nearly 4,000 members of the Society and their friends were present. The bands of the Scots Fusilier Guards and of the Royal Horse Guards attended and performed selections of music during the evening.

Proceedings of Institutions.

METROPOLITAN ASSOCIATION FOR PROMOTING THE EDUCATION OF ADULTS.—The fourth annual gathering for athletic sports will be held at the Crystal Palace, on the 1st July next, to commence at half-past one o'clock punctually. The sports will include flat races, 100 yards, 300 yards, and 500 yards, and one mile, throwing the cricket ball, running high jumps, running long jumps, hurdle races, putting the stone, throwing the hammer, a sack race, 100 yards, concluding with a consolation hurdle race of 200 yards with ten hurdles. The prizes vary from 5s. to 15s. Members of Institutions connected with the Metropolitan Association who intend to compete must send in their names to the Secretary of the Institution to which they belong on or before June 24th. Referees and umpires will be appointed by the committee. No prize will be given unless at least five duly qualified candidates contend for it. Not more than four members of any one Institution will be allowed to contend for each separate event. These sports being solely intended to give encouragement to exercises of strength and skill among the members of the Institutions in Union with the Association, professionals, or any whom the referees may deem ineligible, will be rigorously excluded. There will be the usual attractions of the Crystal Palace, with a balloon ascent, singing by a choir of 300 voices, brass bands, &c.

THE PARIS EXHIBITION.

There are few of the classes on the English side better fitted than that which includes ores and minerals, rough iron, and other metals, tools, china clay, fire bricks, tea-trays, nails, pins, needles, and buttons. The space was totally inadequate to the number of exhibitors, so that several sections have necessarily been split in two, and placed part in this court and part in that of machinery; iron tubes, springs, buffers, iron gates, nuts and bolts afford instances of this. A similar remark will apply to carpets, which, for want of wall space elsewhere, are

placed in the machinery court, where also are, in this case according to the classification, carriages, saddlery, harness, fishing tackle, archery appliances, crucibles, and filters. Those who wish to examine all the specimens of British floor cloth, must not omit to pay a visit to the food department, which is also an appendage of the machinery court.

The British section of class 40,—"Raw materials produced by extraction and their products," contains a choice collection, more remarkable for intrinsic goodness than for quantity or show; the ores are generally well chosen and well arranged; of other minerals there are scarcely any except china clay, which is said to be in demand in France, and coal, which is largely represented. The exhibitors of raw iron, steel, railway and other shaped iron and steel, wheels and axles, specimens of rivetted work, iron and tinned plates, copper in every form, lead, tin, and their compounds, tubes, joints, machine-made bolts and nuts, wire and wire-work are numerous, and most of the specimens exhibited interesting. There is also a fine though not a large show of cutting and other tools, saws, files and springs, and cut-steel goods, corkscrews and similar articles being placed here, and not with cutlery, in the furniture group.

One of the finest illustrations of a grand industry is the collection of ores, metal, and drawings of the great Northumberland and Durham (W.B.) lead works, arranged by a gentleman well known, and formerly a member of the Council of the Society of Arts, Mr. Thomas Sopwith. These works extend over about two hundred square miles, and produce from 8,000 to 9,000 tons of lead per annum. The chart of the works shows the seven-mile level, from Allendale to Allenheads, opened eight or ten years since, and the strata and workings are well illustrated by diagrams. The minerals of the district are arranged in scientific order.

Another exhibition which attracts great attention is that of Messrs. Matthey and Johnson, of Hatton-garden, who show two of the finest platinum apparatus for the rectification of sulphuric acid in the exhibition, besides a number of smaller apparatus and ingots of the same metal, several beautiful arrangements for analytical operations, and a rare collection of preparations of the precious and rare metals. The contents of Messrs. Matthey and Johnson's cases are said to be of the value of £20,000.

While on the subject of metals, machinery, and hardware, it will not be out of place to pay a visit to the water-side, where Great Britain has a noble exhibition of marine engines, apparatus, and nautical objects of various kinds. This portion of the exhibition is easily reached by passing under the quay, either beneath the steel bridge near the French lighthouse, or by the tunnel on the English side. The visitor will there find two large ranges of buildings, one occupied by the French the other by the English commission; on each side there is one large shed devoted to marine engines and apparatus, and both are admirably filled, well arranged, and well lighted. On the French side there are more large actual machines than on the English.

The Admiralty and the Trinity House are splendidly represented at the exhibition, but a portion of the contributions of the former, including artillery and nearly the whole of those of the latter establishment, are not here, but in the machine court, within the main building or in the park. The Admiralty has sent an extensive series of models of about eighty vessels belonging to the navy, to illustrate British ship-building since the introduction of the screw propeller. They include vessels of all classes—two and three deckers, frigates, corvettes, gun boats, iron-plated ships, turret ships, dispatch boats, and transports, and all are made to the same scale, namely, a quarter of an inch to the foot, and exhibit a strange variety of form, showing how the necessities of the service and the views of ship-builders have modified the lines of our floating castles. The Board of Admiralty

also shows a fine pair of marine engines, of 350 horse-power, on the expansive principle, with surface condensers, made by Messrs. Penn and Son, of Greenwich, for H.M.S. *Sappho*; a model of the engines, of 11 horse-power, made by the same firm for the *Mermaid*, and the *Northumberland*; and a launch engine and boiler complete, also by Penn and Sons. The board also shows the engines of a steam launch in their place in the machine court; these consist of two pairs of high-pressure engines, of the total nominal power of six horses, manufactured by the firm of Maudslay, Sons, and Field.

The launch in which those engines are fixed is 35 ft. long by 11 ft. 6 in. broad, and the swift movements of a little craft on the Seine, and the readiness with which she is manœuvred with the aid of her twin screws, afford great admiration. She carries a rifled 12-pounder at her bow, to show her quality as a member of the Royal Navy of England.

Besides this steam launch, there are exhibited a mail pinnace, a cutter, jolly-boat, dingy, gig, and various kinds of life-boats.

The Admiralty shows a fine collection of models illustrative of the system of construction of iron ships, and of the general fittings of men-of-war; specimens of the food prepared by the Government itself for the use of the navy, and a collection of flags, charts, books, &c.

The collection of models exhibited by Captain (R.N.), Messrs. Napier, Laird, White, the ship-building companies, and other establishments, is large and fine, and makes an admirable pendant to the series of Admiralty models.

Amongst the large number of interesting objects retained in these sheds must be mentioned the new and international commercial signals, the series of diagrams illustrative of the regulations of Lloyd's register, a noble life-boat, rocket apparatus, rafts, and all kinds of arrangements for the saving of life from shipwreck.

The British Commission has established a light to the convenience of passing to and from the boats, and a short time there will be a crowd of yachts and boats, and all descriptions around it.

Other nations have some specimens of naval construction in the water here, amongst which are six or seven steam launches.

A new object of interest has recently appeared in the centre of the exhibition; in the inner garden is a polygonal building, the upper story of which is destined to receive the crown jewels of France; the lower portion of this pavilion is devoted to the exhibition of the metric weights, and measures of all the exhibiting nations, occupying a compartment of the polygon, and in the same order as the sectors of the main building devoted to them.

The number of persons visiting the exhibition is very large, although the weather for some time has been far from attractive. There has, however, been an improvement in the latter respect, and a corresponding increase of numbers, during the last few days.

OPENING OF THE GALLO-ROMAN MUSEUM AT SAINT GERMAIN.

A considerable portion of this fine old château has been restored in the spirit of the original plan of the time of François Premier, thus sweeping away the whole of the additions made by Mansard in the time of Louis XIV. The new portions—for they are almost rebuilt—give an excellent idea of a stronghold of the renaissance, although the form is peculiar, being that of a pentagon instead of the more common parallelogram. When completely terminated—a work which will occupy a dozen years at least—the structure will have a very imposing effect.

The museum was opened by the Emperor on the 12th instant. The following account of its contents and arrangement is abstracted from the *Moniteur des Arts*:

In the first *salle* are collected specimens of wrought flint articles, found with bones of extinct species of animals; bones carved, engraved, hollowed, and otherwise fashioned for religious or domestic purposes by the hand of man; a fine collection of flint weapons, presented to the Emperor by the King of Denmark; objects obtained from the sand of the basin of the Seine; and the discoveries of M. Boucher de Perthes in the valley of the Somme.

The second *salle* is devoted to megalithic sepulchral monuments, the dolmens, monoliths, and other works of the first age of stone construction, together with the more artistic flint weapons, and bone instruments, and the first rude specimens of the potter's art of France. These objects are classed by groups, according to the provinces from which they are derived; and opposite the cases which contain them are models, one-twentieth of the real size, of the principal dolmens of the period beneath which the greater portion of these relics have been found.

The third *salle* is entirely occupied by one of these reproductions, although the model is on the scale already named; this is the celebrated Tumulus Dolmen of Gavrinis. Who shall decypher the mysterious characters engraved on the granite of the inner walls of this antique structure? Who shall find the key to these hieroglyphics, the strange turns and contortions of which resemble somewhat the primitive sculptures of India or the decorations of Central America?

The fourth *salle* contains Gallic inscriptions and medals, and is the last of the series at present open on the lower floor. Access is obtained to the upper story by means of the staircase of François I., which M. Eugène Millet, the architect, has restored with great taste and skill.

In the first *salle* above is the collection of Lacustrine antiquities. The age of stone has not exhausted its productions, for here we find flint hatchets, arrow heads, knives and tools, with implements made of bone, tortoise-shell, and hard woods; but the era of bronze begins to show its works. Stone gives place to bronze, and we find swords, hollow hatchets of various forms, collars and necklaces; large poignards have taken the place of javelins and other weapons of that class, as the tomahawk or club of the savage. The nearer we descend towards the historic period, the more numerous become those relics of the Helvetic lakes. Not only has bronze triumphed over time, but by its side are to be found the most fragile, humble, and apparently the most ephemeral tenets of domestic life, such as fragments of woollen garments and fabrics, fishing nets, hunting apparatus, small objects of the female toilet, and even specimens of human food, such as grains of wheat and barley, preserved by some curious accident.

Another *salle* is devoted to the Gallic period of the time of Brennus, and contains numbers of casques, pieces of armour, for the chest, arms, legs, and other parts of the body, bucklers, belts, arrows, swords, and fragments of all kinds, together with a certain number of useful domestic and other implements.

The adjoining *salle* is devoted to Celtic productions, in which the peculiar taste, fancy, and workmanship of various tribes become apparent; the objects in this department of the museum exhibit the patient work of the ancient inhabitants of the soil, and exhibit in their very forms the individuality of the various tribes manifested over the Celtic soil, the mark, the signature, as it were, of their producers.

The last division is to be devoted to the period of the Roman conquest, but this portion of the museum is not yet completed. It is destined to illustrate not only the Roman conquest, but the domination of the ancient conquerors of the world, and is to contain plans in relief the principal sieges undertaken by the conqueror of the soil, with the original, or, in their absence, *fac-similes* the arms, machines, engines, and weapons employed a practical commentary on the "Commentaries."

The new museum has been opened to the public, and its doors will, in future, remain open on Sundays, Tuesdays, and Thursdays, between the hours of eleven and five. It will, however, only be actually closed on Saturdays and Mondays, Wednesdays and Fridays being devoted to study, on which days students, and especially foreign students, will have no difficulty in obtaining an admission.

The museum of St. Germain is an important addition to the attractions of Paris, especially for the archaeologist.

Fine Arts.

KENSINGTON MUSEUM.—The plaster cast taken by Signor Brucciani from the portal della gloria of the Cathedral of Santiago, Spain, has been temporarily put up in the Kensington Museum. It is difficult to over-estimate the interest and value of this magnificent work, executed by Master Matthew, a native Spanish sculptor, about the year 1188. The student of architecture and of ornamental art will recognise in this portal—which is supposed to have been wrought as well as designed by Master Matthew—a combination of diverse historic schools. The draperies and the type and treatment of the figures are in some parts Byzantine, yet the Romanesque and Lombardic style is dominant in the rude vigour of the handling, in the naturalism of the forms, and in the bold use of the grotesque. The insertion of griffins and other monsters at the base of the columns is characteristic of churches in Verona and other cities in Northern Italy. Mr. Street has engraved this grand portal as a frontispiece to his volume on "Gothic Architecture in Spain." He describes the Cathedral of Santiago as of "extreme magnificence and interest." Of the triple portal now reproduced in the Kensington Museum, Mr. Street writes as follows:—"It is now necessary to say something about what is to an architect the chief glory of this noble church—its grand western entrance, fitly called the *Portico della Gloria*. On the whole, with no small experience to warrant my speaking, and yet with a due sense of the rashness of too general an approval, I cannot avoid pronouncing this effort of Master Matthew's at Santiago to be one of the grandest glories of Christian art." The most remarkable portions of the work are the tympanum and the archivolt. Round the latter are ranged figures of the four-and-twenty elders that encircle "The Last Judgment," which occupies the tympanum. More correctly speaking, however, this bas-relief represents, not "The Last Judgment," but "Christ in Glory;" hence the name which the portal bears, "*Della Gloria*." The treatment of the subject accords with prescribed art, or rather ecclesiastical custom—Christ in the centre, the emblems of the four Evangelists attendant around, and beyond angels and the multitude of the heavenly host. Lady Eastlake records the fact that "Christ in glory is seen frequently over the side doorway of early Gothic churches of the 11th and 12th centuries." Mr. Street considers it probable that the entire portal was the handiwork of Master Matthew, unaided by assistants. He assigns a period of twenty years to its execution; the same time was taken by Ghiberti in the execution of his famed bronze doors to the Baptistery in Florence. Mr. Street sees in Master Matthew's work both conformity to custom and precedent, and yet freshness and originality. It is interesting to know that the same qualities are present in the works of the Pisani in Italy, and that from the same causes. Art was in both instances alike in transition from conventionalism and tradition to nature. The execution has the vigour, and even the rudeness, which usually accompany the struggle for independence. Mr. Street reports that on the original portal "traces everywhere remain of the old delicate colouring with which the sculpture was covered." This plaster cast from Santiago, acquired for Kensington, may be followed as it has been

preceded by other like reproductions. The cost, which is considerable, is expended in the cause of art education. The general policy of the department in this matter was indicated by Mr. Cole, in the discussion which ensued on the paper read by Mr. Fergusson before the Society upon Indian Architecture. Mr. Cole then said "the public money had been already employed in obtaining casts of the finest objects in Italy, Spain, and France. We had recently imported into this country, at a cost of between £2,000 and £3,000, a cast of the beautiful gate of the convent of Santiago, in Spain; and, if we were to have these casts from Spain, it would be well to have them from India also. This was the more important when it was recollected how rapid was the destruction of such works in that country."

ARUNDEL SOCIETY.—This society has been seeking to promote the knowledge of art in some new channels. In addition to its usual reproductions from pictures, it has latterly been anxious to lead the way in the publication of faithful memorials of Italian monumental works. All students know that some of the most valued products of Italian art take the form of sepulchral monuments. These architectonic and sculpturelike works are often not only masterpieces for modelling, but also frequently admirable as polychrome decoration. Hence it has been thought that the process of chromo-lithography would enable the Arundel Society to give at once trustworthy and popular reproductions of monuments, which, though long renowned, remain necessarily unknown to the general public. Drawings, both pictorial and to scale, have been made for the approval of the Council. It may also be mentioned that in the Society's rooms, Bond-street, have been on view for some time past, accurate water-colour copies of the several compartments of John Van Eyck's masterpiece at Ghent, "The Adoration of the Lamb." The Council propose shortly to enter on the arduous labour of reproducing this famed work through the medium of chromo-lithography.

COLLEGE OF APPLIED ART, PARIS.—It will be remembered that out of the fine exhibition of decorative works prepared by the Union Centrale des Beaux Arts, and held in the Palais de l'Industrie in the year 1865, there arose a proposition to create a regular college for pupils in the applied arts, which was announced at the time in the *Journal*. The first step was then taken towards the realization of the project by the purchase of a piece of ground for the intended college in the Avenue Philippe Auguste, between the Quartier Saint Antoine and Vincennes. The suggestion received the sanction of the Minister of Public Instruction, and, we believe, of the Emperor, and it is now stated that the preliminary measures have been taken, and that the establishment of the new college will be proceeded with without delay. The intention is to give to the youth of all classes intended for the artistic industries a thorough classical and literary education (classical in the art sense, probably, only), and at the same time to afford them full opportunities of practising the manual operations connected with applied art. The college will receive both boarders and out-of-door scholars. The establishment is to include special museums devoted to each of the great epochs of the history of art, that is to say, of antiquity, of the middle ages, of the renaissance, and of the four Louis, ending with the sixteenth; also a museum of Eastern art, and a library. In addition to these there are to be conservatories for ornamental plants; a department of artificial plants and flowers, for the study of arrangement; cabinets of physics, chemistry, natural history, &c.; a museum of contemporary art, in which will be exhibited at certain seasons specimens of the most remarkable works of the day. Lastly, besides schools for the daily study of drawing, painting, modelling, carving, &c., there will be a number of ateliers which will be accorded gratuitously to the first artists in each class on condition that they allow the pupils to be present during certain fixed hours of the day, when they are engaged in producing works which are to serve as models

for industrial art. Six of these ateliers are already decided on, namely—one for modelling and carving of the human figure and animals, to be presided over by M. Barye, a very able sculptor; an atelier for chasing metals, and the manufacture of goldsmiths' work and bronzes—the brothers Fanniere; one for the decoration of porcelain, faïences, and enamels—M. Claudius Popelin; another for designs for paper-hangings—M. Poterlet; a fifth for decorative painting—M. Moynet; lastly, an atelier for composition and decoration of fabrics, carpets, and furniture; to which no name is yet attached. The scheme is to construct the college to receive 500 resident pupils, and 100 students, with separate chambers. The duration of the course of study is proposed to be fixed at six years, with a uniform charge for pupils of all ages of 1,700 francs per annum. It may be mentioned in addition that the society also intends to maintain its present museum and gratuitous conferences in the Place Royale, for the benefit of those actually engaged in artistic industries. The projectors and supporters of both establishments are Parisian manufacturers or art designers, aided by the Minister of Public Instruction and the Marquis de Moray.

Commerce.

SUGAR AND COFFEE IN BRAZIL.—Mr. Consul Morgan, in his commercial report on the trade of the port of Bahia (Brazil) for the year 1866, states that sugar, though formerly almost entirely the product of slave labour, does not appear to have suffered from the complete abolition and cessation of the slave traffic, seeing that the exports of last year amounted to fully 48,000 tons, whilst the average of the preceding twenty-five years was only about 41,000 tons. Of the total amount exported, about 36,000 tons went to Great Britain, or a channel port for orders; 1,200 tons direct to France; 2,700 to Sweden; 2,700 tons to Portugal; 3,000 to the United States; and the remainder to the River Plate, Holland, Germany, and Spain. The proportion of the different qualities of sugar produced has considerably altered of late; planters have found out that it is not worth their while to make the better qualities, the difference not paying for the trouble and delay, and now but seldom take the pains of claying their sugar—another confirmation of the mischievous effect of the scale of sugar duties, in not only destroying motive for improvement, but in actually inducing the planters to make inferior sugars. In consequence of this, less than one-fourth of the whole crop now consists of "whites," about one-fourth of "clayed browns," and above one-half is raw sugar. The crop of coffee for the year 1866 was considerably below that of 1865, being only 69,200 bags, against 99,700 bags in 1865; but still the crop was an average one, the returns of the last twenty years, from 1846 to 1865, giving an average of only 43,201 bags. The value of coffee has been less affected than other articles, the price throughout the year having ruled from 5-250 dollars to 5-600 dollars per arroba, the average price being 5-400 dollars per arroba. This does not include "washed" coffee, which only comes to market in very small quantities, and is mostly shipped to France. Of the 69,200 bags exported, 33,000 were sent to France; 13,700 bags to Great Britain and to the Channel for orders; 9,400 bags to Gibraltar for orders; 4,800 to Germany; 4,300 to Genoa; 2,700 to Portugal, partly Lisbon, for orders; and 1,200 to the United States.

SUGAR.—The proportion of each description delivered for home consumption at the port of London in the first sixteen weeks of the year 1867 has been as follows:—British West India, 27,266 tons; Beetroot, 6,475 tons; Manila, 5,036 tons; Cuba Muscovado, 4,515 tons; Havana, 4,060 tons; Porto Rico, 3,050 tons; Madras,

* A Bahia bag of Coffee contains 4 arrobas, or 133 lbs., whilst at Rio de Janeiro a bag contains 5 arrobas, or 166 lbs.

2,735 tons; Mauritius, 2,696 tons; Penang, 1,451 tons; Brazil, 1,388 tons; Bengal, 1,291 tons; Java, 19 tons; total, 59,932 tons.

Colonies.

POSTAL COMMUNICATION.—The postal conference of representatives of different colonies, which met at Melbourne, has come to the following decision:—"That, in order to establish a postal system affording regular fortnightly communication by three lines, *via* Brisbane and Torres Straits to Singapore, *via* Melbourne and South Australia to Suez, and *via* New Zealand to Panama, with the necessary branch services, the six colonies represented at this conference should contribute a moiety, not exceeding £200,000, of the total cost, in the following proportions, viz.:—Victoria, one-fourth; New South Wales, one-fourth; New Zealand, one-fourth; Queensland, one-seventh; South Australia, one-twelfth; Tasmania, one-fiftieth." According to this, the three first colonies will have to pay £50,000 each, and the remaining £50,000 will be divided between the other colonies as follows:—Queensland, £28,571; South Australia, £16,666; and Tasmania, £4,000. As regards Western Australia, the conference decided that, as there was no representative present, the contribution of that colony to the postal service should remain as before. The next important matter was the question of routes, upon which a series of resolutions were agreed to. Their purport is as follows:—The Adelaide mails, by the Suez line, to be delivered by the ocean steamer at Kangaroo Island, and conveyed to and from that island and Port Adelaide by a branch service. Branch steamers are also to leave Melbourne and Sydney for Adelaide and Tasmania on the arrival of the Panama and Singapore steamers. The whole of the branches are to be done at a speed of not less than nine miles and a-half per hour, and the several branch steamers are to take their departure on the outward journey within six hours of the arrival of the trunk-line steamer; whilst, if necessary, they are to await her arrival for a period not exceeding three days beyond the date of her being due.

THE MANUFACTURES OF NEW SOUTH WALES.—The total population of the colony of New South Wales is about 430,000, chiefly engaged in gold mining, coal getting, agriculture, pastoral pursuits, and commerce. Notwithstanding the limited labour-market, there have sprung up in this colony more than two thousand manufactures and works of various kinds. Some of these are connected with, and dependent on, agriculture; as the manufacture of hay-pressing, reaping, and chaff-cutting machines. Then there are boiling down establishments, soap and candle manufactories, and other places where the raw materials produced by the pastoral interest are worked up. There are also three distilleries, sugar refineries, and breweries. There are upwards of 300 places for plastic manufactures and the production of building materials. There are about a hundred works for brass, iron, lead, and the manufacture of machines. The manufacture of boots and shoes by machinery near Sydney employs many hands; and there is a large variety of miscellaneous works, the number of which will advance naturally as population increases. A great proportion of clothing too is made in the colony. It is a significant fact that while the population has increased about one-hird during the last ten years, the manufactures and works have increased sevenfold.

Notes.

BRITISH ASSOCIATION OF GAS MANAGERS.—The fourth annual general meeting of the members of this association will be held at the School of Art, Waverley-street, Not-

tingham, on Tuesday, Wednesday, and Thursday, the 11th, 12th, and 13th June. Thomas Hawkesley, Esq., C.E., President of the association, will occupy the chair. On the Tuesday, at the morning meeting, at twelve o'clock, an inaugural address will be delivered by the president. At the evening meeting, at seven p.m., a lecture will be given by Dr. Lethaby, on "The Utilisation of the Residual Products of the Manufacture of Coal Gas, with especial reference to the Production of Aniline Colours from Coal Tar." On the Wednesday the chair will be taken at eleven a.m.; various papers and communications will be read. At five p.m. the members will dine with the President, at the George Hotel, Carlton-street. The Thursday will be occupied by visits of the members to various works and places of interest in Nottingham and the neighbourhood.

THE INTERNATIONAL CONGRESS OF ANTWERP.—This meeting is appointed to open on the 25th of August, and to close on the 1st of the following month. The meetings will be under the honorary presidency of the Minister of the Interior, and will take place in the rooms of the Royal Society of Harmony, on the Place of the old canal at Antwerp. The congress will coincide in time with the triennial exhibition of works of art and with the communal *fêtes*; it is said that nearly all the historical and archaeological celebrities have inscribed their names as members of the congress, and that the greater part of the European governments have appointed official representatives. The King of the Belgians has promised to attend the congress in person. It may be convenient for the members of the Society of Arts and the readers of the *Journal* to know that adhesions are to be addressed to the *Secrétaires-Généraux*, 19, Rue du Mai, Antwerp.

MEETINGS FOR THE ENSUING WEEK.

Journal of the Society of Arts.

FRIDAY, JUNE 7, 1867.

Announcements by the Council.

THE LATE SIR THOMAS PHILLIPS.

At a meeting of the Council on Monday last, the 3rd instant, the following resolutions were passed:—

Resolved—"That the Council desire to record their deep regret at the death of their much esteemed and excellent chairman, Sir Thomas Phillips, whose long and valuable services as a member of this Council, and as its chairman for several years, have largely contributed to promote the interests and usefulness of this Society.

"That a copy of this resolution be sent to Mr. William Page Phillips (nephew of the late chairman), together with the expression of condolence and sympathy of the Council with him and the rest of Sir Thomas Phillips' family."

ANNUAL CONFERENCE.

The Sixteenth Annual Conference between the Council and the Representatives of the Institutions in Union and Local Boards will be held on Wednesday, the 19th June, at Twelve o'clock, noon. The Right Hon. HENRY AUSTIN BAILEY, M.P., will preside.

The Council will lay before the Conference the Secretary's Report of the Proceedings of the Union for the past year, and the Results of the Examinations, and the Programme of Examinations for 1868 will also be considered by the Conference.

The following suggestions of Subjects for Discussion have been received from various quarters, it being understood that in putting them forward the Council express no opinion whatever upon them:—

1. Whether the means at present available for the promotion of Primary Education are sufficient to qualify the working classes to take advantage of the Secondary Instruction offered by Institutes to Adults?

2. Whether provisions should be inserted in the Manchester Education Bill, now before Parliament, which would authorize grants to be made to Evening Schools and Classes?

3. Whether, considering the valuable results of the co-operation which the Royal Horticultural and Geographical Societies, and certain public companies, have afforded to the Society of Arts in extending the sphere of its Examinations, the like co-operation cannot be aimed from other societies and companies, especially in the Royal Agricultural and Botanical Societies?

4. Whether any additional means can be devised to induce the Institutions to form District Unions, with paid Visiting Officers, in connexion with the Society of Arts?

5. Whether additional interest in the Final Examinations might not be excited by the establishment of Special Prize Funds in the District Unions, to which Supplementary District Prizes might be added by the Society of Arts?

6. What means can be adopted by the Local Boards to secure a larger number (a) of Candidates from the Artizan Class at the Final Examinations, and (b) of Female Candidates at the Elementary and Final Examinations?

7. Whether it would be expedient to adopt, as far as possible, one specified text-book for each of the subjects in the Final Examinations?

8. Whether it would be expedient that the Society of Arts should decline to recognize an Elementary Certificate of any given year as a Pass to the Final Examinations of the same year?

9. Whether it is desirable, in the Elementary Examinations, to have one set of papers instead of two, as at present, but with two grades of Certificates, according to the merit of the Candidates?

10. Whether, in order to secure uniformity in the Previous Examinations, the Society of Arts should furnish an Elementary Paper (distinct from the Ordinary Elementary Examinations) to meet the case of those Candidates who may not, in any previous year, have obtained Elementary Certificates?

11. Whether any steps can be taken by the Society of Arts, in order to prevail upon the Science and Art Department to grant Honorary Teachers' Certificates to those gentlemen who shall be recommended by any Public Educational Board?

12. How can the Institutions or District Unions assist the movement now being made by the Society of Arts to send selected Workmen to Examine and Report upon the Paris Exhibition?

Secretaries of Institutions and Local Boards are requested to send, as soon as possible, the names of the Representatives appointed to attend the Conference, and early notice should be given of any other subjects which Institutions or Local Boards may desire their Representatives to introduce to the notice of the Conference.

As the subject of National Education is of peculiar interest at the present time, and several topics of great importance to the Institutions are proposed for discussion at the Conference, the Council hope that each Institution and Local Board will not fail to appoint one or more Representatives to express its views.

Secretaries of Institutions are requested to forward *at once* by book post, copies of the last Annual Reports of their Institutions.

EXAMINATIONS, 1867.

The following corrections should be made in the List of Prizes and Certificates given in last week's *Journal*:—

In Political and Social Economy, the 1st prize of £5 to No. 1473, Edward T. Sims, jun., Southampton Athenæum, clerk. No second prize awarded.

To the note marked (+) add, "or the candidates were disqualified for receiving prizes."

In the List of Certificates, No. 1489, Hadfield, James, should have been described as of the Staleybridge M.I.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object, and on their recommendation, have passed the following minute:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government, to facilitate the visits of skilled artisans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed, in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

HIS ROYAL HIGHNESS THE PRINCE OF WALES, President of the Society, has presented a donation of Thirty Guineas.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

TWENTY-THIRD ORDINARY MEETING.

Wednesday, June 5th, 1867; THOMAS WEBSTER, Esq., Q.C., F.R.S., in the Chair.

The following candidates were proposed for election as members of the Society:—

Asprey, Charles, jun., 166, New Bond-street, W.
Byass, Robert B., Nevill-park, Tunbridge Wells
Cross, John C., 12, Barnsbury-road, Islington, N.
Edwards, Robert, 35, Lower-street, Deal.
McMillan, John, 7, Westminster-chambers, S.W.
Meeson, Alfred, 5, Westminster-chambers, S.W.
Mounsey, Ewart Simon, 5, Raymond-building, Gray's-inn, W.C.
Rossiter, William, F.R.G.S., Linden-villa, Tottenham.
Rutherford, Charles, 32, Oakley-road, Southgate-road, N.
Sykes, John, 280, Regent-street, W.

The following candidates were balloted for, and duly elected members of the Society:—

Armit, Lieut.-Col. Louis, R.E., Golden Cross Inn, Charing-cross, S.W.
Davidson, James, Laboratory Department, Royal Arsenal, Woolwich, S.E.
Lucas, Frederick, 26, Maddox-street, Regent-street, W.
Salvin, Anthony, 4, Adam-street, Adelphi, W.C.
Whitley, Nicholas, Truro, Cornwall.
Williams, Michael, 35, St. James's-place, St. James's-street, S.W.

The Paper read was—

ON THE WATER SUPPLY OF THE METROPOLIS, IN RELATION TO THE CONSERVANCY OF THE THAMES AND ITS TRIBUTARIES, AND THE DEMANDS OF THE WATER COMPANIES.

BY J. BAILEY DENTON, Esq.

It may be in the recollection of some of our members that I have on several occasions raised discussion within these walls on the subject of water supply in connection with land drainage, river improvements, and the necessity of an accurate record of rainfall.*

On these and on other occasions I have treated the subject as one of national importance, affecting not the metropolis only, but extending to the whole country, being impressed with the facts, which are daily becoming more generally acknowledged, that the rainfall is getting positively, though gradually, less in quantity, from the disafforesting of woodland, the improved cultivation of the soil, and the drainage of lands and districts; that, although, by the drainage of land, we gain an increase of water in the winter season, we suffer a diminution in summer; and that the sewerage of towns is corrupting our rivers and streams in their transit through the country to the sea, proportionately as the sewerage of towns extends and the summer flow of rivers becomes less. All these influences are connectedly producing a great change in our water system, demanding the serious attention of the people and the protective care of the Government; and we cannot shut our eyes to the truth that our population is increasing at the rate of 200,000 a year, or 3,845 a week, while the area of our island remains the same.

I have not hitherto laid any great stress upon the diminution of the rainfall, because it has always been considered that the position of Great Britain, in its proximity to the wide Atlantic Ocean—from the surface of which evaporation takes place to an unlimited extent, increased by the warm current of the Gulf stream—is such as to make any diminution of rainfall resulting from re-

* Journal of the Society of Arts, December 14th, 1855; January 15th, 1856; and November 24th, 1865.

vaporation from the surface of our island a matter little moment. The valuable essay of Professor recently published in the *Journal of the Royal Agricultural Society of England*,* however, places the in so clear a light, and raises its importance eyes of scientific men so considerably, that the cannot long remain one of indifference to ple at large. He shows, by very simple dia- formed from the records kept at Greenwich h are reliable, I presume, and have been kept riod extending over 50 years—that a “consider- ecrease” in the amount of rain has taken place hat period. The Professor, when comparing infall within the period from 1814 to 1864 e, states that during the first 25 years the mean fall was 26·69 inches, or 1·44 inch above the mean of the 50 years, and that during the last s the mean fall was 23·75 inches, or three inches in the first 25 years. He also shows that, during ing periods of seven and fourteen years, from 1863 inclusive, the decline in quantity has been ws:—

Years.	Inches.	Mean of 14 years. Inches.
1815–1821.. Mean rainfall	28·7	.. 28·3
1822–1828.. ”	27·9	.. 26·1
1829–1835.. ”	24·3	.. 24·7
1836–1842.. ”	25·1	.. 24·6
1843–1849.. ”	24·1	.. 24·0
1850–1856.. ”	23·8	.. 23·8
1857–1863.. ”	23·7	.. 23·8

we deduce from this instance that the rainfall nerally declining, we cannot reject from con- tion the counterbalancing circumstance that land age, which is taking place all over the country, urges into the rivers from the land a *larger* ity of water than found its way to them before age, and more than is actually lost to the rivers e lessened rainfall. In fact, if the whole area of Thames watershed consisted of wet land, which l be benefited by drainage, we should, in the aggre- be considerable gainers by the extension of the ice; but the wet lands form only the smaller por- of its area, and therefore we can only apply the ntage to that lesser extent. Moreover, it is hardly eary to repeat, the water of drainage issuing from lay lands is not constant; it is for the most part urged in the winter months, when both soil and air re frequently in a state of saturation and when vegeta- is dormant, and ceases to flow in summer when oration is active and the demands of vegetation can lly be satisfied. Hence it is that the underground ation of drainage, which we adopt for the ameliora- of our heavy wet lands, adds to the derangement dy caused by the improved cultivation of the surface the spread of population. It extracts from the soil, in , the water which has hitherto been retained to sten the air of summer and to support our rivers. s the floods of winter and the droughts of summer both increased, and the hygrometric condition of the osphere altered so much as to make us acknowledge t England is undergoing an appreciable change of nate.

Before passing from this point, it is right to state t if drainage consisted only of subsoil drainage the tendency would be to render floods less frequent, be- ase the water, having to pass through the soil inter- diate between the surface and the drains, would be zed and detained in that depth of earth on its way to

the outfall, and if the rains were not repeated too quickly the sudden congregation of waters would be prevented. But as the primary object of drainage is to get rid of excessive wetness as soon as possible, the outlets and watercourses are now so much improved, and are every day becoming more and more improved, by straightening and widening, that the expected detention is more than counteracted by the facility afforded for the immediate discharge of both surface and drainage waters, which are precipitated into the valleys with a suddenness unknown fifty years back. The importance of this consideration can hardly be excluded from the immediate subject before us—the supply of water to the metropolis—for when this excess of water from drained lands, discharged as it is in winter, is added to the increased flow of springs and water- courses natural to that season of the year, it must be obvious that the surplus so placed at our disposal at one season to compensate for scarcity at another is a gift we ought not to reject. It is no part of the present purpose to specify with accuracy the quantity of water so placed at our command, though it is much to be regretted that the special terms of the Water Supply Commission prevented the Duke of Richmond and his colleagues from carefully inquiring into the capabilities of storage existing, and the means of making reservoirs, within the Thames basin. It is, nevertheless, of the first importance that these points should be under- stood by the country, for in the inexhaustible powers of storage exists the solution of the whole question of supplying London with economy. No one who has critically investigated it doubts the abundance of water existing in the basin of the Thames, though the preva- lent opinion with the general public is the reverse.

While asserting that if storage be resorted to the excess of the driest winter will more than compensate for the drought of the driest summer by which it may be succeeded,* I am content to place before you the following facts in support of the assertion:—

Out of the average mean rainfall of 26 inches due to the Thames basin, it requires only $\frac{1}{4}$ of an inch of the surplus of winter from the whole watershed of the Thames, or $1\frac{1}{4}$ inches of rainfall from one moiety of the watershed, to satisfy the whole popu- lation within it. Or, to put the matter more prac- tically, as it will only be necessary to collect water for six months of the year, half an inch of rain falling upon an acre of land is sufficient to supply two persons with 30 gallons each per diem for six months, and no winter passes by in which there does not run off to the sea, without serving any useful purpose, in excess of the mean summer flow of the river, at least five times the quantity required to meet the supply of the metro- polis in the dry times of summer, when the river cannot fairly part with any portion of its volume; and this, or any portion of it, may be stored for compensation to the river if reservoirs were properly constructed for the pur- pose. To appreciate our present position it should be understood that the water companies are continuing the unexampled practice of abstracting from the Thames 60,000,000 of gallons daily, which may be increased to 100,000,000, independent of what is now desired to be taken by the East London Water Company, without any compensation whatever, although it is acknowledged that the volume of the river (which should always be maintained, if possible, at a standard flow,—say of 450 millions of gallons per diem) is sometimes reduced, in dry summers, after the companies have abstracted their supplies, to from 300 to 350 millions of gallons.

Now I pause to ask why this one-sided practice

* When speaking of the rainfall in years of scarcity we have been led into confusion by the published returns being tabulated according to the calendar year, whereas the summer flow of rivers depends on the preceding winter's rainfall. No month's rain has so much influence on the supply of summer as the fall of the previous October. If we have a wet October and an average wet winter the springs will be replenished, and the flow of our rivers increased.

should be continued. Is it right, with a declining rainfall and a declining summer flow, we should allow one-fifth, which may be increased to one-third, to be abstracted in summer without compensation, when, by simply storing the surplus of winter, we may secure the means of returning to the river any quantity equal to that abstracted from it, when the river volume falls below a certain recognised standard height? Unfortunately, the Legislature, in its wisdom, by granting, in the first place, to the five water companies drawing their supplies from the Thames, the power of abstracting 100 millions of gallons daily, and in the next by being a party to the payment of £6,400 a-year by those companies to the conservators* for considerations it is difficult to understand, has sanctioned and condoned this unexampled proceeding; and although the public interests have been prejudiced thereby, it is now too late to cancel these powers altogether. But it does not follow that a rule should not be made which shall be binding on the companies in future, obliging them to provide compensation for whatever water is taken from both the Thames and the Lea, when their volumes have fallen below a given standard at the points of abstraction, be the reduction what it may.

If this proposal were adopted we should hear no more of a scarcity of water, and the superior character of the river Thames and its tributaries would be restored.

I began by stating that among the influences conspiring to disturb the water economy of the country the sewerage of towns by the pollution of our streams was having a considerable weight, and as the prevention of this evil will test to the utmost the powers of conservancy, it may be well to make some general remarks, which may have their bearing upon the Thames and the Lea too.

The water-closet system has now acquired such a firm place in our household arrangements, that we cannot anticipate the use of any other vehicle but water for the discharge of sewage from towns of any size, however we may modify the system in villages, and for suburban and country houses, by the adaptation of earth closets, which are most excellent expedients, and will no doubt come into extensive use where combination in sewerage is not necessary to effect the duties of the scavenger. It is the daily increasing use of water-closets in towns, and the immense growth of special trades and manufactures using and abusing our streams, that sets aside all previous provision.

It is admitted that rivers, to answer their full natural purpose, must serve as drains to receive the liquid refuse of their watersheds, as well as sources of water supply for the towns within them; and, perhaps, the most difficult problem to solve in the present day is, the obligation to maintain, at one and the same time, these two objects—reconciling, as it were, the antipodes of riparian service. The conclusion, I believe, to which the intelligence of the country has arrived is, that, abstractedly no water can be used with impunity for drinking purposes after sewage has been mixed with it. Or, to give the matter a practical bearing, it may be more truly said that, as soon as sewage can be detected by chemical analysis to exist in an appreciable degree in the water we are called upon to drink it is a vital error so to use it. Of course, as rivers can but maintain their natural position as the drains of their watersheds, it is not possible altogether to exclude objectionable liquid refuse; and as some of the best chemical authorities

declare that the water of rivers, and the Thames among the number, if mixed with only a small proportion of clarified sewage, remains substantially innocuous, if advantaged by the oxidizing influence of a run of several miles before use, it is only necessary to determine with precision what proportion of organic matter, animal and vegetable, shall be allowed to exist in drinking-waters when delivered to the consumer. If we arrive at this we practically fix the chemical standard of quality, and it then remains to determine by what means it shall be maintained. Even in their aboriginal state all rivers received organic matter in the shape of decayed vegetation, and if we ascend to the higher portions of rivers for our water-supply we cannot exclude a certain amount of both animal and vegetable refuse, although the towns are comparatively small and few which are situated at the heads of rivers, and there are generally geological conditions of soil which favour the absorption of liquid matter. It is not for me to suggest what should be the standard of quality, but seeing that different companies taking water from the same spot,* deliver to their consumers water with very different proportions of organic matter, it is manifest that some rule should be fixed and accepted, and from which the water companies should not depart.

Professor Frankland stated, in his evidence before the Thames Navigation Committee of last year, that the quantity of organic matter in the Thames varied from three quarters of a grain minimum to two grains per gallon maximum, and with such data it would not be difficult to fix a standard of purity.

Of all methods of purification the application of sewage to land is the only one to which science accredits the power of arresting objectionable matter, though the mode of application is found to govern the extent to which the process succeeds. Sewage discharged from towns by gravitation, or lifted by mechanical power to high grounds, if it passes simply over the surface of land without passing through it, retains a large part of the noxious matter, and cannot be considered to be in a fit condition to mix with river water used for drinking. This view applies with increased force the nearer the irrigated lands approach the river. The absorbent powers of vegetation are doubtless very great, but they are not sufficient in themselves to appropriate the impurities held by water in suspension as well as in solution. Moreover, vegetation has not equal vital powers all the year round to seize and appropriate the fertilizing elements which are its food. It has its seasons of rest as well as of growth, and at such times its extractive and retentive capabilities are very small. When vegetation, however, grows on a deep bed of free soil, through which the sewage can descend and percolate, satisfying the vegetation, we possess the best means of purification, its perfection depending quite as much on a sufficient depth of subsoil through which the effluent water must descend as upon the action of vegetation.

We must not confuse the system of irrigation which allows of the effluent water to sink into the subsoil, satisfying vegetation with the "dumb-well" or cesspool mode of disposing of sewage in its normal state. In the first case, the effluent water which would pass into the river as clarified sewage, if "run over land" sinks into the soil and replenishes the springs, after being utilised on the surface; whereas, in the second case, sewage is dropt into holes of porous ground, which retain the solid matter to fester under foot, and allow liquid sewage to sink into the earth without doing good whatever to vegetation.

Where free soils affording natural drainage are to be obtained, the nearest approach to them is to which underdrainage has been or may be applied, the drains in such case affording artificially a means of discharge, when the level of the drains is rendered similar in character to that which takes place in a

* The following are the payments made by the water companies taking their supplies from the Thames to the conservators:—

By agreement, 1852.		By Act, 1866.	
Chelsea	300	1,000	= 1,300
Grand Junction	300	1,000	= 1,300
Lambeth	200	1,000	= 1,300
Southwark and Vauxhall }	300	1,000	= 1,300
West Middlesex	300	1,000	= 1,300
	1,400		6,400

* See Appendix XIV. to the First Report of the Rivers Commission.

of free soil when the descending water reaches the level of the springs. But as the depth of underground drainage is limited to a few feet, the extent of purification is limited correspondingly, and though to the eye, and probably to the taste in many instances, the discharged water from lands irrigated with sewage may be objectionable, I believe I am correctly stating the fact in saying that such water is seldom if ever free from organic matter. The question which therefore arises, when applying sewage to drained land, is whether the irrigation it undergoes, in addition to absorption by vegetation, is sufficient to allow of the effluent liquid from the drains being mixed with impunity with river water and for drinking. Abstractedly, it is wrong to do so; it, as under many circumstances theory cannot always be carried to its extreme, it will probably often occur that the distance to be travelled by the mixed waters before it will be sufficiently great to effect oxidation and so more all objection. Expediency may thus override principle and sanction the proceeding.

As a rule, it may be assumed that the application of sewage will be profitable in proportion to the command a farmer may have over the sewage he applies. It is to percolate the soil and pass away too quickly, and a sufficient breadth of land may not be covered at a dressing. The irrigated land may, in fact, be far too open to free for the farmer's profit, though not for purification. To irrigate undrained clay lands is opposed both to profit and purification, for it cannot be expected that it is already suffering from excess of the rainfall will be met by double the quantity of sewage-liquid being poured over it and added to the rainfall. The same lands which will bear any amount of irrigation with an increase of produce of good quality, though the effluent water may remain polluted; but to apply sewage to land needing no escape through the soil is to "put the impost on to make the weeds grow ranker," for the drainage can only be coarse and very inferior in character. When we have had more experience in sewage farming—and it will doubtless become a special business, the Rivers Commissioners have pointed out in their reports—it will probably be found that a system of drainage admitting of the plugging of the outlets, so as to hold back the water in the soil for a time, and to flush the drains, will be adopted. In some parts of England a plan is adopted for water irrigation with success. Thus we are compelled to view the application of sewage to land in three ways:—

First. That sewage run over a surface of land which is neither natural nor artificial drainage to assist vegetation in retaining the deleterious elements, altogether is to secure that degree of purity which will allow of being discharged into rivers, from whence may be drawn water for drinking purposes, though the operation may serve to clarify and improve its character sufficiently to allow of its being utilised in rivers for navigation, and many other riparian uses.

Second. That land artificially drained to a depth of a few feet affords, if irrigated, only an imperfect means, in conjunction with vegetation, of separating from sewage objectionable elements.

Third. That where sewage can be lifted to high and dry grounds with a free and porous subsoil, which will admit of its penetration to a considerable depth after it has fed vegetation on the surface, a perfect means of purification may be attained.

With these conclusions as to the utilisation of sewage the steps to be taken to exclude it from rivers when in objectionable condition, we have to consider how they will be acted upon or enforced by the Board of Conservators, under whose care the Thames and its tributaries are now placed; and in my remaining observations I shall content myself by bringing before you the position and duties of the Conservators of the Thames in relation to water supply, and the powers they possess of referring to the five water companies, with whom Parlia-

ment has associated them, water of unobjectionable quality.

In speaking of quality, I am aware that I shall bring to the minds of many the question of *hardness*, which is one of great importance. It forms no feature of my paper on the present occasion, because, as its title implies, it is confined to the Thames and its tributaries, and it is not possible to obtain from these sources any other character of water than that partaking of from 13 to 18 degrees of hardness. If we were comparing the water of the Thames with other and distant sources of supply, offering different qualities of water or different degrees of hardness, the object would be directly pertinent, but I desire to exclude all points which might provoke a discussion on the relative merits of the different schemes now proposed for the supply of water to London, and which would have the effect of diverting attention from the Thames. My own name, indeed, has been associated with a proposal for utilising the upper tributaries of the Thames in conjunction with the storage of surplus waters, in which I still retain the utmost confidence, but I do not appear here to night as an advocate of that project, feeling that I should be abusing my connection with the Council of this Society were I to do so. It cannot be denied that to exclude the question of hardness from any discussion on the supply of water to a great community like that of the metropolis is to omit a very important element, but when you are reminded that its introduction would open up a wide field of argument as to the national policy of abstracting water from one valley to supply it to another, the power of reducing hardness by chemical appliances, and the relative healthiness of hard and soft water—the consideration of which alone would be sufficient to occupy the evening—you will probably concur with me in a desire to confine our attention to the present powers afforded by Parliament for securing to the metropolis a supply of wholesome water from the Thames through the agency of the water companies, with the support of conservancy.

The urgency of the question of metropolitan supply is demonstrated by the fact that while we justly hesitate to take water from the high grounds surrounding the manufacturing districts of the north-west, because the increase of population in those districts is truly prodigious, and in excess of the increase of the metropolis itself, the addition each year to the population of the metropolis is 40,000, which, I need not tell you, alone exceeds the number of people in the majority of county towns in England.

To describe in detail the constitution and duties of the Board of Conservancy of the River Thames would take too much of our time, but it may be useful to state that the Corporation of the City of London, who were the original conservators, transferred their powers and duties to the Board constituted by the Act of 1857, and with them the obligations of an agreement entered into in 1852 with the five water companies drawing their supplies from the Thames, by which £1,400 a year was arranged to be paid by these companies to the conservators "as compensation for expenses incurred by the conservancy in consequence of the works of the companies." In 1864 the constitution of the Board was reorganised, though its duties and jurisdiction were still confined to the improvement and control of the river below Staines. Those duties professedly were the maintenance of the navigation, with jurisdiction over the shores and the uses of the river, and the actual works of the Board extended only to the preservation of the banks, locks, weirs, and other river works essential to navigation, and to the dredging and scavenging of the river itself. Last year the jurisdiction of the Conservancy Board was extended from Staines as far as Cricklade, and the Legislature, considering it expedient that a provision should be made for preventing the pollution of the river, and that the five water companies drawing water from it would be benefited thereby, authorized and imposed the payment of £1,000 a year

should be continued. Is it right, with a declining rainfall and a declining summer flow, we should allow one-fifth, which may be increased to one-third, to be abstracted in summer without compensation, when, by simply storing the surplus of winter, we may secure the means of returning to the river any quantity equal to that abstracted from it, when the river volume falls below a certain recognised standard height? Unfortunately, the Legislature, in its wisdom, by granting, in the first place, to the five water companies drawing their supplies from the Thames, the power of abstracting 100 millions of gallons daily, and in the next by being a party to the payment of £6,400 a-year by those companies to the conservators* for considerations it is difficult to understand, has sanctioned and condoned this unexampled proceeding; and although the public interests have been prejudiced thereby, it is now too late to cancel these powers altogether. But it does not follow that a rule should not be made which shall be binding on the companies in future, obliging them to provide compensation for whatever water is taken from both the Thames and the Lea, when their volumes have fallen below a given standard at the points of abstraction, be the reduction what it may.

If this proposal were adopted we should hear no more of a scarcity of water, and the superior character of the river Thames and its tributaries would be restored.

I began by stating that among the influences conspiring to disturb the water economy of the country the sewerage of towns by the pollution of our streams was having a considerable weight, and as the prevention of this evil will test to the utmost the powers of conservancy, it may be well to make some general remarks, which may have their bearing upon the Thames and the Lea too.

The water-closet system has now acquired such a firm place in our household arrangements, that we cannot anticipate the use of any other vehicle but water for the discharge of sewage from towns of any size, however we may modify the system in villages, and for suburban and country houses, by the adaptation of earth closets, which are most excellent expedients, and will no doubt come into extensive use where combination in sewerage is not necessary to effect the duties of the scavenger. It is the daily increasing use of water-closets in towns, and the immense growth of special trades and manufactures using and abusing our streams, that sets aside all previous provision.

It is admitted that rivers, to answer their full natural purpose, must serve as drains to receive the liquid refuse of their watersheds, as well as sources of water supply for the towns within them; and, perhaps, the most difficult problem to solve in the present day is, the obligation to maintain, at one and the same time, these two objects—reconciling, as it were, the antipodes of riparian service. The conclusion, I believe, to which the intelligence of the country has arrived is, that, abstractedly no water can be used with impunity for drinking purposes after sewage has been mixed with it. Or, to give the matter a practical bearing, it may be more truly said that, as soon as sewage can be detected by chemical analysis to exist in an appreciable degree in the water we are called upon to drink it is a vital error so to use it. Of course, as rivers can but maintain their natural position as the drains of their watersheds, it is not possible altogether to exclude objectionable liquid refuse; and as some of the best chemical authorities

declare that the water of rivers, and the Thames among the number, if mixed with only a small proportion of clarified sewage, remains substantially innocuous, if advantaged by the oxidizing influence of a run of several miles before use, it is only necessary to determine with precision what proportion of organic matter, animal and vegetable, shall be allowed to exist in drinking-waters when delivered to the consumer. If we arrive at this we practically fix the chemical standard of quality, and it then remains to determine by what means it shall be maintained. Even in their aboriginal state all rivers received organic matter in the shape of decayed vegetation, and if we ascend to the higher portions of rivers for our water-supply we cannot exclude a certain amount of both animal and vegetable refuse, although the towns are comparatively small and few which are situated at the heads of rivers, and these are generally geological conditions of soil which favour the absorption of liquid matter. It is not for me to suggest what should be the standard of quality, but seeing that different companies taking water from the same spot,* deliver to their consumers water with very different proportions of organic matter, it is manifest that some rule should be fixed and accepted, and from which the water companies should not depart.

Professor Frankland stated, in his evidence before the Thames Navigation Committee of last year, that the quantity of organic matter in the Thames varied from three quarters of a grain minimum to two grains per gallon maximum, and with such data it would not be difficult to fix a standard of purity.

Of all methods of purification the application of sewage to land is the only one to which science accredits the power of arresting objectionable matter, though the mode of application is found to govern the extent to which the process succeeds. Sewage discharged into towns by gravitation, or lifted by mechanical power to high grounds, if it passes simply over the surface of land without passing through it, retains a large portion of the noxious matter, and cannot be considered to be in fit condition to mix with river water used for drinking. This view applies with increased force the nearer the irrigated lands approach the river. The absorbent powers of vegetation are doubtless very great, but they are not sufficient in themselves to appropriate the impurities held by water in suspension as well as in solution. Moreover, vegetation has not equal vital powers all year round to seize and appropriate the fertilising elements which are its food. It has its seasons of rest as well as of growth, and at such times its extractive and retentive capabilities are very small. When vegetation, however, grows on a deep bed of free soil, through which the sewage can descend and percolate, and thus satisfying the vegetation, we possess the best means of purification, its perfection depending quite as much on a sufficient depth of subsoil through which the effluent water must descend as upon the action of vegetation.

We must not confuse the system of irrigation which allows of the effluent water to sink into the subsoil, and thus satisfying vegetation with the "dumb-well" or common mode of disposing of sewage in its normal state. In the first case, the effluent water which would pass the river as clarified sewage, if "run over land" sinks into the soil and replenishes the springs, after being utilised on the surface; whereas, in the second case, the sewage is dropt into holes of porous ground, where it retains the solid matter to fester under foot, and allows the liquid sewage to sink into the earth without doing good whatever to vegetation.

Where free soils affording natural drainage are to be obtained, the nearest approach to them is to which underdrainage has been or may be applied. The drains in such case affording artificially a means of discharge, when the level of the drains is made similar in character to that which takes place in a

* The following are the payments made by the water companies taking their supplies from the Thames to the conservators:—

	By agreement, 1852.	By Act, 1866.	
Chelsea	300	+	1,000 = 1,300
Grand Junction	300	+	1,000 = 1,300
Lambeth	200	+	1,000 = 1,200
Southwark and Vauxhall }	300	+	1,000 = 1,300
West Middlesex	300	+	1,000 = 1,300
	1,400		6,400

* See Appendix XIV. to the First Report of the Rivers Commission.

free soil when the descending water reaches the of the springs. But as the depth of underground is limited to a few feet, the extent of purification is correspondingly, and though to the eye, probably to the taste in many instances, the discoloured water from lands irrigated with sewage may be objectionable, I believe I am correctly stating the facting that such water is seldom if ever free from the matter. The question which therefore arises, applying sewage to drained land, is whether the soil undergoes, in addition to absorption by vegetation, is sufficient to allow of the effluent liquid from drains being mixed with impunity with river water for drinking. Abstractedly, it is wrong to do so; and under many circumstances theory cannot always resist to its extreme, it will probably often occur that distance to be travelled by the mixed waters before they will be sufficiently great to effect oxidation and so effect all objection. Expediency may thus override principle and sanction the proceeding.

As a rule, it may be assumed that the application of sewage will be profitable in proportion to the command of the farmer may have over the sewage he applies. It erodes the soil and passes away too quickly, and a great breadth of land may not be covered at a dress. The irrigated land may, in fact, be far too open to the farmer's profit, though not for purification. To irrigate undrained clay lands is opposed both to fit and purification, for it cannot be expected that already suffering from excess of the rainfall will be further increased by double the quantity of sewage-liquid being poured over it and added to the rainfall. The same lands will bear any amount of irrigation with an increase of produce of good quality, though the effluent may remain polluted; but to apply sewage to land which cannot escape through the soil is to "put the soil on to make the weeds grow ranker," for the soil can only be coarse and very inferior in character. When we have had more experience in sewage irrigation—and it will doubtless become a special business, the Rivers Commissioners have pointed out in their report—it will probably be found that a system of sewage admitting of the plugging of the outlets, so as to back the water in the soil for a time, and to flush drains, will be adopted. In some parts of England land is adopted for water irrigation with success. As we are compelled to view the application of sewage to land in three ways:—

1st. That sewage run over a surface of land which either natural or artificial drainage to assist vegetation in retaining the deleterious elements, altogether or secure that degree of purity which will allow of the effluent being discharged into rivers, from whence may be drawn water for drinking purposes, though the operation serves to clarify and improve its character sufficiently for its being utilised in rivers for navigation, and any other riparian uses.

2nd. That land artificially drained to a depth of a few feet affords, if irrigated, only an imperfect means, in connection with vegetation, of separating from sewage objectionable elements.

3rd. That where sewage can be lifted to high and dry grounds with a free and porous subsoil, which will allow of its penetration to a considerable depth after it has been removed from the surface, a perfect means of purification may be attained.

With these conclusions as to the utilisation of sewage before steps be taken to exclude it from rivers when in an objectionable condition, we have to consider how the law will be acted upon or enforced by the Board of Conservators, under whose care the Thames and its tributaries are now placed; and in my remaining observations I shall content myself by bringing before you the position and duties of the Conservators of the Thames in relation to water supply, and the powers they possess of authorising the five water companies, with whom Parlia-

ment has associated them, water of unobjectionable quality.

In speaking of quality, I am aware that I shall bring to the minds of many the question of *hardness*, which is one of great importance. It forms no feature of my paper on the present occasion, because, as its title implies, it is confined to the Thames and its tributaries, and it is not possible to obtain from these sources any other character of water than that partaking of from 13 to 18 degrees of hardness. If we were comparing the water of the Thames with other and distant sources of supply, offering different qualities of water or different degrees of hardness, the object would be directly pertinent, but I desire to exclude all points which might provoke a discussion on the relative merits of the different schemes now proposed for the supply of water to London, and which would have the effect of diverting attention from the Thames. My own name, indeed, has been associated with a proposal for utilising the upper tributaries of the Thames in conjunction with the storage of surplus waters, in which I still retain the utmost confidence, but I do not appear here to night as an advocate of that project, feeling that I should be abusing my connection with the Council of this Society were I to do so. It cannot be denied that to exclude the question of hardness from any discussion on the supply of water to a great community like that of the metropolis is to omit a very important element, but when you are reminded that its introduction would open up a wide field of argument as to the national policy of abstracting water from one valley to supply it to another, the power of reducing hardness by chemical appliances, and the relative healthiness of hard and soft water—the consideration of which alone would be sufficient to occupy the evening—you will probably concur with me in a desire to confine our attention to the present powers afforded by Parliament for securing to the metropolis a supply of wholesome water from the Thames through the agency of the water companies, with the support of conservancy.

The urgency of the question of metropolitan supply is demonstrated by the fact that while we justly hesitate to take water from the high grounds surrounding the manufacturing districts of the north-west, because the increase of population in those districts is truly prodigious, and in excess of the increase of the metropolis itself, the addition each year to the population of the metropolis is 40,000, which, I need not tell you, alone exceeds the number of people in the majority of county towns in England.

To describe in detail the constitution and duties of the Board of Conservancy of the River Thames would take too much of our time, but it may be useful to state that the Corporation of the City of London, who were the original conservators, transferred their powers and duties to the Board constituted by the Act of 1857, and with them the obligations of an agreement entered into in 1852 with the five water companies drawing their supplies from the Thames, by which £1,400 a year was arranged to be paid by these companies to the conservators "as compensation for expenses incurred by the conservancy in consequence of the works of the companies." In 1864 the constitution of the Board was reorganised, though its duties and jurisdiction were still confined to the improvement and control of the river below Staines. Those duties professedly were the maintenance of the navigation, with jurisdiction over the shores and the uses of the river, and the actual works of the Board extended only to the preservation of the banks, locks, weirs, and other river works essential to navigation, and to the dredging and scavenging of the river itself. Last year the jurisdiction of the Conservancy Board was extended from Staines as far as Cricklade, and the Legislature, considering it expedient that a provision should be made for preventing the pollution of the river, and that the five water companies drawing water from it would be benefited thereby, authorised and imposed the payment of £1,000 a year

from each company to the Conservancy Board, having rendered it obligatory on the part of that Board to scavenge the surface of the river, in order to the removal therefrom of all substances liable to putrefaction, and to clear the river of weeds, that they might not decay. It would appear, however, that there was some doubt in the minds of the committee which settled the Act whether the presiding authority of the river might not itself be sometimes at fault, for by the fifty-first clause of the Act provision is made for an appeal to the Board of Trade, "should any work executed by the Conservators, in the opinion of the five metropolitan companies, injuriously affect either the flow or purity of the water of the Thames." No works to be executed by the conservators seem to be contemplated by the Act of last year, nor indeed by the Bill of this session, either for the increase or purification of the water of the Thames other than those essential to a proper maintenance of the river for navigation. The actual operations of the Board would appear to be limited to improving and maintaining the navigation and the supply to mills, and in scavenging the river, while its powers are extended to preventing towns and persons from polluting its waters by the discharge of sewage and obnoxious matter. The Act of last year declares that it shall not be lawful for any sewage to discharge into the river, or into any stream connected with it, within three miles of the main trunk (which provision it is presumed will shortly be extended to all the tributaries), and it requires the Conservators to give notice to any person or body to discontinue the discharge of sewage after a certain time named in the notice, which shall not be less than twelve months nor more than three years, imposing a fixed penalty, payable, by any one disregarding the notice, of £100, with a further penalty of £50 a day if the nuisance be continued. With the service of the notice and the legal proceedings against any one disregarding them, the direct action of the Conservators—as respects the purification of the river—ends. They appear to be a valuable medium for enforcing the law.

Though they have the authority to prevent the continued abuse of the river by pollution, they cannot prevent a legitimate use of its waters as population and trades increase, and agriculture may require it; and though they would successfully resist the water companies taking out of the river more than they have parliamentary powers to take, the Conservators have no power to enforce compensation from storage, let the effect be what it may. With powers of so little practical advantage as respects water supply, it is difficult to understand for what purpose the water companies are paying the additional £5,000 a-year, which, by the Act of 1866, they are collectively bound to pay. The first contribution of £1,400 a-year may be taken as payments incident to, though not directly for, the abstractions at Hampton, which in some degree affected the navigation below; but with respect to the last payment of £5,000 a-year, there exists no similar reason, inasmuch as the companies have no additional powers given to them, either to take more water, or to abstract it higher up, where it would affect the navigation above Staines. The payment could be understood if, by any actual expenditure on the part of the Conservancy Board, the additional quantities of water the several companies have yet the power to take were positively secured to them, without raising any objection on the part of the public interested in the river. If, on the contrary, the £5,000 a-year is, as I have supposed, required to maintain the river banks and works for the upper navigation, it would only appear right that those interested in, and to benefit by, that navigation should find the money, particularly as the Act recites that "if the duties of the conservancy of the upper part of the Thames were efficiently performed, the traffic on the navigation, and the income derivable therefrom, would considerably increase." With this expectation, there

could have been no difficulty in raising any required amount of money by a loan, repayable by instalments, extending over a sufficient length of time to realise the assumption. As it is, however, the interests of the public have been sacrificed, and, as I have before stated, a prejudicial compromise effected. The water companies doubtless consider that they are paying their £1,000 each for the privilege of drawing their water from the Thames as it passes by Hampton in whatever condition it may be secured to them by the proceedings of the conservators of the river, and that they are exonerated by the payments they make from compensating the river for any quantity they may in future take out of it, within the limits of 20 millions of gallons each, even though the flow of the Thames may from other causes be materially reduced. No doubt the companies are justified in so regarding the arrangement, but it remains with the public to say whether some modification must not take place.

The quantity of water yet to be taken from the Thames under existing Acts is 40 millions of gallons daily, and this is likely to be increased by the 10 millions required by the East London Water Company. This company, with the New River Company, have absorbed the entire dry weather volume of the Lea, after the navigation has taken its prescribed quantity, and the company is obliged to come to the Thames for its immediate wants, no effort having been made in the valley of the Lea to store its surplus waters.

So great is the increase of demand for water in the metropolis, that it may be but a very few years before the maximum quantity which the companies are empowered to take may be reached. In the meantime winters may succeed, like the last, in which the valleys of the Thames and its tributaries may be in a state of inundation, involving local losses of an immense aggregate amount; and it may be fairly asked whether a compromise such as the Legislature has sanctioned shall continue to have effect without an effort being made so to balance excesses that the evil of one season may be turned to the benefit of the other.

It is only in this way that we may satisfy the question of quantity, and, having placed before you in earnest terms, the difficulties resulting from the Parliamentary compact I have referred to, I leave it in your hands for consideration.

I will now recall your attention to the question of quality. It may be found that the towns called upon by the conservators to discontinue the discharge of the sewage into the river may evade purification by the adoption of imperfect works. Some may have recourse to irrigation on river-side meadows without drainage whereby, as I have already stated, the effluent water may flow into the river clear to the eye, though almost as foul as before. Others will adopt different expedients, but all will abstain as long as they can from incurring the extra expense of lifting the sewage to high grounds, or even of under-draining the irrigated lands (which, as I have said, should always be insisted upon where natural drainage does not exist), to secure the necessary absorption which is essential to that degree of purification required by water-drinkers.

In the meantime, the contributions of the water companies will be paid to the Board of Conservancy, and

* We may see on the Lea a very telling instance of the way in which money may be spent in proceedings carried out in obedience to an Act of Parliament, without producing the intended effect. As described in the words of the Rivers Commissioners: "By an Act passed in 1854, the New River Company obtained powers to lay down intercepting sewers through Hertford, to construct works for treating the sewage by the liming process, and to convey the effluent water past the New River head into the Lea." These works cost £21,000 and £700 is paid annually to carry out the process. "The effluent water passes away clear," and being mixed with the water of the Lea, is drunk by the water consumers of the metropolis, though the people of Ware, the town immediately below Hertford, find it "clear sewage" "a constant cause of complaint." It is declared by the Rivers' Commission to be sewage still, with the disadvantage appearing to be different to what it really is.

implies an obligation strengthened by each succeeding year.

As never, I believe, been publicly suggested, though the proposal is worth consideration, that, as the authorities of the towns now discharging their sewage into the river may fairly content themselves with, and satisfy the ratepayers by adopting, the cheapest disposal of the sewage which shall legally meet the terms of the notice, it may be served upon them, it may be only right for those who are requiring such a purification of the river as shall make it fit to drink should pay something towards the difference between the cost of carrying out the existing operations which shall legally satisfy the conservators' notice and those which will satisfy the water-works of the metropolis.

Compared with the application of sewage to lower lands by gravitation, the lifting of sewage on to high lands not only involves a greater first cost, in modifying and extending the outfall works and in erecting engines, pumping-stations, and appliances, but remains as a constant outlay the cost of fuel, wages, &c., which form no items when irrigating is in question. Does it not appear reasonable that some contribution of this outlay should be paid by those who receive a degree of purity beyond simply clarifying the river so that it shall satisfy navigation and other uses.

I put the matter in a tangible form, and having in the towns of Banbury, Oxford, Reading, Abingdon, Wallingford, Windsor, and the many other towns on the Thames and tributaries above Hampton, I may say that the annual cost of raising the sewage of 100 persons to a height of 100 feet, and to a distance of five miles, may be fairly taken at £5,000 a year. Now, as the £5,000 a year, payable to the conservators under the Thames Navigation Act, 1866, consists of the price of the water drinkers, though it passes through the hands of the water companies, is it not fair that the whole or a part of the annual outlay required for lifting sewage of such towns as are situated above the point extracting the supply to the metropolis, should be out of this fund? This amount (£5,000), if so added, would go a very great way towards satisfying the question of quality—assuming that the towns referred to could meet the question by taking upon themselves the extra first cost of the necessary works.

My suggestion appears equitable and right in many respects, and I leave it for your consideration, merely adding that by apportioning the £5,000 a year among the towns according to population, the conservators would be relieved of the anomalous position of receiving payment from the water drinkers of the metropolis, without making any positive effort to raise the quality of the river to a standard of purity.

In bringing these remarks to a close, it will not be necessary for me to assure you that I am conscious of their imperfect nature. With a subject so large, I have endeavored more difficultly in bringing what I have had to say into a small compass, than in finding matter to report the few objects I have desired to make prominent. I have nevertheless managed to curtail my observations to limits which have left good time for discussion, which is the more desirable as this meeting is the last of the session.

DISCUSSION.

Mr. S. C. HOMERSHAM said, if he understood the paper correctly—and he had taken some pains to do so—the question raised in it was, whether a large body of flood water should be impounded in the upper tributaries of the Thames, or in the Thames itself, and let out in dry seasons for the purpose of giving a more equable flow to the river. The writer of the paper had not said very clearly that this was his view, and he had not said, for instance, the quantity of water which ran in the river in flood times, and the quantity that

flowed down in dry seasons, nor the area of the watershed of the Thames, nor, in fact, any exact data to go upon by which it could be ascertained whether such a proposition could be dealt with or not. All data of this kind—whether studiously avoided or not he could not say—certainly were kept out of the paper, and there was no proposition before the meeting except a general one that flood waters should be impounded in ordinary reservoirs and given out in seasons of drought. If they were to discuss that question intelligibly they must have data and figures of an exact and positive character, whereas the only figures of any kind given were (and he believed that they were correct), that there was an average rainfall of twenty-six inches in the watershed of the Thames, this being assumed from the ascertained average of the rain-fall being twenty-four inches at Greenwich. The area of the watershed of the Thames down to the point where the water companies took their supply was 3,500 square miles or thereabouts; and the area of the watershed below Hampton to the mouth of the river was about 1,500 square miles, making altogether 5,000 square miles as the watershed of the whole river. But before discussing the proposition which was made, it was necessary to know what was the character of that watershed. There were some large districts of country upon which, from the physical configuration, and from the character of the soil and the rock of which they were composed, water no sooner fell than it ran off; and within a few hours after a heavy rain all the water, or nearly all, flowed off through the brooks and streams, and came down in a heavy flood. He knew districts where very large impounding reservoirs might be dry at 9 o'clock in the morning, and if there were heavy rain would be quite full and running water to waste at three o'clock the same afternoon. That was the character of many soils, but there were others where there might be heavy rain, even to the extent of 1½ inches or more in the hour, but where no water at all would appear in the streams, the whole being absorbed by the drainage-ground instantly, and sinking beneath the surface, and where one might go over the ground when the rain was over and almost say that it would not be wet, and there would be no flood or water at all even in the valleys and on the lowest ground. He knew a district in one patch, of 272 square miles, where neither river, spring, nor stream was to be seen on the surface at all, the whole of the water which fell upon it being immediately absorbed into the soil and rock of which the district was composed. Now, the having to deal with a soil of that character, or with one where the water ran off immediately, were two very different things, and therefore they must examine not only the area but the character of the drainage-ground of the Thames. Of the 3,500 square miles which he had given as the area of the drainage-ground down to Hampton, about 1,200, or a third-part, consisted of chalk, a character of soil so porous that no sooner did rain touch it than it was absorbed; there was also another portion of the drainage-ground where the sub-soil was green sand, which was also another absorbent rock. Below Hampton Court he found 600 square miles of the drainage ground to be chalk, so that in round numbers it was correct to say that one-third of the total drainage ground consisted of a soil that absorbed water as soon as it touched it. Dealing first with the portion above Hampton, the first place where the chalk appeared in the river course was at Maidenhead, and then the river ran on for about 30 miles, following the sinuities of the river, on chalk, after which the chalk disappeared. The level of the water standing in the saturated chalk at Maidenhead was 60 or 70 feet above Trinity high-water mark, and the level of the chalk saturated with water in the Chiltern range, beginning near and above Luton and Tring, was 450 feet above Trinity high-water mark. The variation in the line of the saturated water level in the highest point was something like 40 to 80 feet in the year, being highest, generally, about the end of June, and lowest at the end of December. There was a saying in

those districts "as the days lengthen the springs strengthen," which was really true, as up to about the longest day the water gradually rose, and from that day to the shortest day, as a general rule, it fell, the variation on an average, and taking one season with another, being about 40 or 50 feet. Now, a cubic foot of dry chalk would absorb $2\frac{1}{2}$ gallons of water on an average; all chalk was not exactly of a like quality, but about one-third of the bulk of chalk consisted of small pores, and, as a cubic foot would be equal to $6\frac{1}{2}$ gallons, it would take up on an average considerably more than two gallons of water, so that fully a third of the cubic contents of saturated chalk was water. This was very important in considering the question before them, because, seeing that there were 1,200 square miles above Hampton, where the whole rainwater falling upon the ground was absorbed, and that there stood at the Chiltern ridge chalk saturated with water to the level of 450 feet above high-water mark, and to 70 feet at Maidenhead, it followed there was an average depth of 260 feet of chalk above high-water mark saturated with water, which was equal to a column of water itself 86 feet in height, so that literally there were 1,200 square miles of chalk in the drainage ground of the Thames, above Hampton only, with free water in it to the depth of 86 feet. This was a matter of fact—there was no question of theory about it. The tops of the hills of the Chiltern ridge varied from a thousand to six or seven hundred feet high, and taking the average at five or six hundred feet the dry ground would average 200 feet down to the saturated chalk, and below that there were 360 feet of saturated chalk, equal to 86 feet of free water. A very simple calculation would show that this was equal to about 18 trillions of gallons of water, or to a supply of 200 millions of gallons of water per day for 246 years. This could be clearly demonstrated. No doubt few persons present were sufficiently acquainted with the facts to know that when standing on those chalk hills, so dry on the surface and covered with very scanty herbage, they were really standing above quite a sea of water. That was the state of the case with regard to the large portion of the drainage ground of the Thames before described. There was water already stored in the chalk equal to a supply of 200 million gallons per day for 246 years, even if it were never replenished. Now, taking the rainfall at 26 inches, it would be but a small amount and an under-statement to say that 10 inches went to the lower depths. From an experience of 25 years in sinking wells and so on in the chalk, he (Mr. Homersham) believed it was much nearer 20 inches, but he was content to take it at 10 inches, which would give these 1,200 square miles as being replenished with a quantity equal to 408 millions of gallons of water per day for every day in the year. Now, with such an enormous natural storage reservoir so amply filled and so amply supplied, and so constantly replenished with water from the clouds, why should they try to impound in artificial reservoirs the flood waters for dry seasons? In his opinion it would be a very unwise proceeding, because every one who had had anything practically to do with water impounded in large reservoirs should know that it was not of a wholesome quality for the supply of large towns. For instance, the water in Loch Katrine was, no doubt, very free from mineral matter, but it contained a considerable quantity of organic matter, and decomposing organic matter, especially in warm autumn seasons, that was unwholesome, while before it got to Glasgow from Loch Katrine a portion of the oxygen combined with a portion of the organic matter, and the water became partially de-oxygenized. However, leaving that subject, he (Mr. Homersham) considered that to store water in open reservoirs and then lower it down the Thames, would be very unwise, because water standing in these artificial reservoirs became of necessity mixed with fallen leaves, faded blossoms, the droppings of animals, and other impurities, and became of worse

quality even than the flowing water so contained. These artificial impounding reservoirs were usually in the most barbarous manner. They often had several feet of mud and filth at the bottom, and there were no means provided for cleaning the reservoirs, and the water became full of conifers and other organisms, in fact such as no water company would supply for domestic use. The proper way of supplying the water to the companies from the Thames would be to get at this water naturally stored in the pores of the chalk and to bring the supply of London, which would prevent interference with the navigation. This was being done in spite of every obstacle so unnaturally put in the way many years past by government. They had been told the papers of the poisonous character of the water had been given by the companies at different times to London, and the number of the persons who were poisoned by the water; that was due, he believed, to the improper interference of the Government, or those acting under their authority, made up blue books, and had prevented the companies from supplying pure water to London. Perhaps the lower part of the Thames below Hampton was 600 square miles of chalk to be found in the proportion of it, and one water company (the Kent Company) had already abandoned the river and gone to the source for supply, and now supplied water from a source to 32,000 houses, or a quarter-million persons for some time had not taken a drop of water from the river, but had gone to the chalk and obtained the water direct from wells. The New River Company was gradually resorting to springs, or to wells sunk in the chalk. Such water at its source was of the best quality for the purposes of a water supply, being perfectly free from all organic matter, free from dead, and of one even temperature throughout the year. In the summer it was comparatively warm, 52° Fahr., while Thames and other surface waters were 68° or 70°, and in winter it was about the same. Thames water would be 33° or 34°, so that it was liable to freeze in the pipes. The only thing that could be said against the water was that it was hard, but by a simple process, which had been in operation for many years, it could be reduced from 2½ degrees to 3½ degrees of hardness. There was no interest of the health of water-consumers, he hoped, would be no attempt to impound water in reservoirs on the Thames, but that the river waters should be left as they were, and resort should be had to the natural reservoirs in the chalk for the supply.

The Rev. J. CLUTTERBUCK thought it was quite useless to make any calculations in reference to the supply founded on the average rainfall, as the water only ought to be taken; and he also objected to the average which had been taken by Mr. Bailey Denham deduced from the observations at Greenwich. He emphatically denied that the rainfall had decreased during the last fifty years; observations of his own for sixteen years, and of others on whom he could rely for twenty-nine years, showed rather an increase than a reverse. This seemed a principal point in the question, and he therefore wished to remove what seemed to be an assumption, which might unnecessarily frighten people. Nor did he think that anything which could be done in the way of cultivation of land, draining, or cutting timber, would in the least appreciable degree affect the rainfall, which was due to the Atlantic and Indian oceans. The storage of water in the Upper Thames might be very easily accomplished, as there was great power of storage in the river itself. He concurred in the good deal which had been said by Mr. Homersham in reference to the springs in the chalk, and believed it might be proved that the greater portion of the water which passed over Teddington lock at some seasons was derived from that source. If any one could see the miserable ruined inheritance on which the Thames

vacancy had entered, they would know that a great deal more money must be spent before the river could be stored to its proper condition, and one very great point stored would be the saving of the water by improvement in the navigation. With a little patience he believed they would see that they need not go elsewhere for water, but that Old Father Thames would be true to his great mission, and give them a good and abundant supply.

Mr. R. RAWLINSON, C.B., said he had listened with considerable pleasure and interest to the remarks of the preceding speaker. The amount of rainfall was dependent upon causes of so vast a character, that he was perfectly satisfied that anything man could do would only modify it to an infinitesimal extent. Cultivation, clearing of land, and draining, would have but a very fractional influence on the fall of rain. Averages for even fifty years were not to be relied upon, but whether the rainfall had decreased or not they might take it for granted that nothing they could do would influence it either for good or evil. They could, however, economise that which fell on the surface; and he might mention one fact to Mr. Homersham which he might add to the facts which he had stored up with regard to the great gathering grounds of chalk, which he supposed to be of such vast absorbent powers. It had been his (Mr. Rawlinson's) duty to obtain accurate observations, extending over a considerable period of time; they had been obtained by men on whom he could thoroughly rely, and the results were very surprising. Mr. Muir, of the New River Company, Mr. Greaves, of the East London Company, Mr. Beardmore, a gentleman of world-wide reputation in such matters, and Mr. Jas. Simpson, were his informants. The Thames had been gauged accurately for a series of years over Teddington Weir by Mr. Simpson, and the daily volume of water which flowed down ascertained, with the exception of excessive floods, and those were known approximately. The other gentlemen had carried out a series of observations on the River Lea with reference to the water supply and also for settling the legal rights of the several proprietors. The result was that, out of an average of 25 inches of rain, taking that as the datum, four-fifths of the entire volume could not be accounted for by measurement in any way, and they could only come to the conclusion that 20 inches out of the 25 passed again into the atmosphere. That result was so startling that he himself was sceptical at first until he had thoroughly investigated it. Now, as far as his investigations went, the minimum rain-fall in the valley of the Thames, and also pretty generally over England, and indeed all over the world, as compared with the maximum, was as one to two, and, as Mr. Clutterbuck had said, in any calculations it was necessary to take the minimum. Now, deducting one-third from the average would give the minimum, and adding one-third would give the maximum. So that, avoiding fractions, the minimum in the valley of the Thames would be about 16 inches, and the maximum about 32 or 33 inches. Down to 16 inches, therefore, they must bring their calculations, and he did not suppose Mr. Bailey Denton contemplated making reservoirs for more than 365 days' supply, about 120 to 200 days being generally considered sufficient by engineers. He regretted that a writer so well able, from his large experience, to handle this subject, should have used the word "compact" as describing the agreement made in the Act of Parliament between the Thames Conservators and the water companies. He did not think it was a proper word to use as applied to such a subject. He thought it rather implied that the public had been "sold" by that "compact." The CHAIRMAN did not think the language implied that at all.

Mr. RAWLINSON said he entirely justified the demand made upon the water companies; he had had as much to do with it as anyone, and if his advice had been taken

the sum would have been doubled. Previously, the companies had Parliamentary powers to take the water without paying anything for it, and in the meantime the river was going to ruin in every possible way, weeds growing, channels choked up, shallows silted, all sorts of garbage allowed to be thrown in, and no scavenging whatever. The stipulation was that the Conservators should restore the river and cleanse it, so that in fact the companies had a cheap bargain of it, and the public were benefited by the transaction. With regard to the application of sewage, that also was a speciality of Mr. Denton's, but he thought a little further inquiry would teach him that sewage was clarified by a proper application to clay land, even if not underdrained, which Mr. Denton stipulated for. He (Mr. Rawlinson) by no means said the land should not be underdrained, but he could assure Mr. Denton that some persons, practically acquainted with sewage irrigation, would prefer, from their experience, to irrigate claylands without underdraining, if Italian rye grass, which was the most profitable crop, were to be sown. In this grass the roots were near the surface, and the silica of the clay combined with the sewage and tended to precipitate it. Experience showed that when such irrigation was judiciously carried on, although the process of assimilation did not proceed equally at all times, there was not a day in the year, winter or summer, when you could not beneficially place sewage on the land, and when that sewage would not come clarified from that land. That had been proved, and it was a very important fact. He sincerely hoped that Parliament would follow the advice given in the paper, and make sewage irrigation imperative on all towns which now tainted rivers with it, for it never would be done until the law was stringently applied. Parliament had yet to learn the immense importance of following up laws by strict supervision, so as to see that those laws which affected the whole community were effectively carried out.

Mr. HOMERSHAM said, with reference to the disappearance of four-fifths of the rainfall, that not only was he aware of that fact, but he knew a large district where it disappeared altogether.

Mr. RAWLINSON remarked that if the water disappeared from the surface, it must come out again somewhere. The only conclusion he could come to was that it was lost by evaporation.

Mr. HOMERSHAM said the water went to the sea through underground fissures, being carried off by springs below high-water mark.

Professor VOULEMER said he understood Mr. Denton to say that there were great difficulties in the way of sewage water that passed over land being perfectly purified. There was no doubt some truth in this statement, but if sewage farms were really properly managed the purification of sewage might be rendered perfect; inasmuch, however, as there were not these model establishments, and in many cases the water simply flowed over the land, the purification was generally very imperfect. It was far more difficult to get the water through the soil than was generally believed, especially on clay lands, where it often ran through the cracks, and did not actually go through the soil at all. Where properly managed, however, sewage water, after passing through the soil, became quite fit for ordinary uses and for drinking. There was one other purely chemical question on which he would make an observation—the organic matter in water. The writer of the paper thought it would be desirable to have a fixed standard for the amount of organic matter which should be present in water for drinking, and Mr. Homersham said that some water was perfectly free from these matters. Chemically that was not correct, as no natural water was absolutely free from organic matter, although to a non-chemical eye it might appear so. He thought it would be desirable to have something like a standard of purity, but, without knowing the kind of water, it would be extremely dangerous to fix such a

standard. He had had water for analysis which contained very little organic matter, and yet which he had no hesitation in pronouncing totally unfit for drinking, whilst other samples, which contained three or four times as much organic matter, were useful and wholesome. It was not so much the amount as the quality of the organic matter which was of importance, and hence the difficulty of fixing the standard by quantity. In practice, a very good test of the presence of injurious matter was to bottle off a portion of the water for a fortnight or three weeks, and then examine it, when, if the organic matter, however small in quantity, were in a state of decomposition, there would be an unpleasant smell. This was perhaps as good as any chemical test which could be applied. There were great difficulties in estimating with precision the quantity of nitrogen, as suggested by Professor Frankland. If that could be done it would be a step in advance, but as that could not be done, there would be very great difficulty in fixing a standard for the amount of organic matter which might be tolerated in drinking-water.

Mr. BORTY, in explanation of a discrepancy between the amount of rainfall as stated in the report of the Royal Agricultural Society and that given elsewhere, stated that the reports were issued a considerable time after date. He also remarked, in reference to the cultivation of Italian rye grass, that where it was attempted without sewage irrigation, the soil was very much exhausted, in some cases causing the total failure of the succeeding crop.

Mr. NEATE, M.P., wished to call attention to what had been said by Mr. Homersham, which had made a considerable impression on his mind, about the unwholesomeness of water which had been stored. He had been one of those who had attached great importance to the storage of water in the valley of the Thames, but it now appeared from what had been said that this would be of very little value, because the water would not be wholesome. He thought this would much depend, however, on the way in which the water so stored was kept up. Was it to be merely by the overflow of the water in the river, or by the turning into it of streams in the summer season? If it were kept up in that way what advantage would be gained by turning those streams into reservoirs which would not be gained by turning them into the river itself? Mr. Homersham seemed to value the great chalk reservoirs, not so much by what they gave out as by that which they kept in. They all knew, however, that there was an immense amount of water in these chalk reservoirs, but its only value was when it was released therefrom.

Mr. TOWLS gave his opinion in favour of reservoirs, and remarked that it would be no new thing, there having been in the neighbourhood of Standlake and other places above Oxford (until draining and other agricultural works had destroyed them), immense natural reservoirs, which served to feed the stream in summer seasons, and which he, as a miller, now felt the want of very much. He also thought that better regulations for ensuring a perfect flow and scouring of the river would be very beneficial.

Mr. BAILEY DENTON, in reply, said that he had carefully avoided referring to what was known as his own scheme, or the project with which his name was connected, which was the utilisation of the upper streams of the Thames in connection with storage. That would explain the omission of many details, as Mr. Homersham and Mr. Rawlinson would understand. The same explanation would apply to Mr. Clutterbuck's remark that averages of rainfall had very little to do with the question. He had himself frequently stated (he believed in that room) that the minimum rainfall was the real basis to be taken. With regard to the exception which had been taken to the use of the word "compact," he thought he could hardly have chosen a word less liable to an offensive interpretation; but, if it was thought desirable, would withdraw it, and substitute the term "agree-

ment" or any other term that might be preferred. Mr. Rawlinson's authority stood as high as that of any man in relation to the question of irrigation by sewage, but if he had understood him aright in saying that the drainage of such land was not necessary, he must, with the greatest respect, give a contradiction to such a statement. He considered it absolutely essential. With regard to the storage of water, he did not say that such reservoirs as Mr. Homersham had referred to would not be objectionable, but he had not at all gone into the question of what reservoirs would be desirable, if it were necessary to supply London direct from reservoirs. The whole of his observations on that and former occasions had tended towards conserving in winter the surplus water, in order to compensate the river in summer for what was taken out of it, the water not being supplied direct to the consumers from the reservoirs, but returned to the river. That perhaps would satisfy the gentleman (Mr. Neate) who wished him to refer to that point. At the same time, he must not be understood to hold that reservoirs could not be constructed in the valley of the Thames, in which water might be preserved for drinking purposes. He believed they knew very little about what might be done in that way, if there were proper means adopted for purifying the water, and that the conservation of water in large reservoirs of sufficient depth would tend to improve its quality, rather than to injure it.

The CHAIRMAN, in proposing a vote of thanks to Mr. Denton, said, that of course anybody with the experience of Mr. Homersham or Mr. Rawlinson could have added a great deal to the paper, and so could the writer himself had he not been restrained by the time at his disposal. It seemed to him that the paper had brought before them the prominent question on which the public must pronounce a decision before long. As to the question of the rainfall, he quite agreed with what Mr. Rawlinson had said, but that, after all, was a secondary consideration. The operations of nature were conducted on so vast a scale that anything man could do would not produce any perceptible effect, but still he should be very sorry if the local observations which had been conducted with such great care were discontinued, because they were of very great value. If, however, they were told that improved drainage increased the floods and the droughts, he said these questions were not worth a moment's consideration with reference to the great question of the supply of water to the river. They who knew what took place in the north and west of England, especially in mountain districts, knew very well that it was the great mass of water brought from the ocean to which they looked; and although the rain was largely absorbed before it came to this more southern locality, still it was practically to that source that we must look for a supply of water. Therefore, although it was very wise to make these observations, for all practical purposes they might be disregarded. He was reminded by this discussion of the answer which a celebrated engineer gave to the question of what use rivers were. He said their only use was to supply canals. So, in relation to this question, he should say that the use of valleys was to store water. He believed that there was an unbounded supply for the wants of man if they took the minimum water supply of any district, which, as had been said, might be taken at 16 inches; if all that were stored, it would be abundant for generations to come. He believed, from what he had heard in the course of professional experience—for he had no practical acquaintance with the subject—that water stored in large bulk was improved in quality. Where it was stored in small bulk and in shallow depths, it might become impure, but in larger quantities it was different. The observations of Mr. Homersham on the way in which water was stored in the chalk were most interesting, but, if this could not be got at, it was evidently wise to store what could be conveniently got at in the valleys. He would only say one word with reference to what Mr. Rawlin-

n had said on the question of the "compact." He ought the arrangements then made were very advantageous and desirable. If the water companies obtained large quantities of water from the river, which was to be brought into a proper condition, it was only right that they should contribute to the maintenance of it from which they derived this benefit. There was no larger question still in which many were interested, *z.*, the right of rivers to the water shed of the district. They had had that before them on a recent occasion with reference to the drainage of the Fens. There the water of the district had become essential to the maintenance of the rivers if navigation were to go on. In modern times, however, the question of navigation had become of less importance than drainage, although in an earlier stage of civilisation it might not have been so. Now that the main traffic of the country was carried on by means of railways—navigation, drainage, and water supply ought all to be kept distinct. The time was not far distant when, as they had seen with reference to the water shed of the Thames, the inhabitants of particular districts would become extremely jealous of water being transferred from one watershed to another. A river had a right to the water naturally belonging to it, and the inhabitants of the district had a right to the use of it; but, inasmuch as they benefited from that very use, why should they not be taxed for the maintenance of it in a proper condition? Those were questions upon which we were just entering; and he believed that the paper they had heard was one great step towards the solution of them. Those who knew what the state of the Thames was some years ago, when old London-bridge existed, and Lambeth was supplied with water drawn from the river between Waterloo and Westminster bridges, would see that anything which was paid for the privilege of drawing the water from beyond the tidal influence was money equitably levied. Tidal influence was in fact created by the removal of old London-bridge; and there being now a totally new state of things, the money paid for their advantage was rightly paid, for a good supply of water to the metropolis could not possibly be bought at too high a price.

ARTIZANS' VISITS TO PARIS.

At a meeting of the Council of the Birmingham Chamber of Commerce, held on Wednesday, the 29th ult., a letter was read from the Society of Arts, inviting the co-operation of the Chamber in sending skilled artisans to Paris, "to study the Exhibition and principal manufacturing establishments of France." Mr. W. C. Aitken, a member of the Society of Arts Committee for promoting the visits, was present by invitation, and explained the merits and advantages of the Artizans' Visits to Paris, as projected by the Society of Arts; he also pointed out that much benefit might be anticipated from the reports the artisans sent were bound to write, and the advantages an inspection of the factories and workshops the Society would afford them facilities of visiting; he also showed the advantages which might be expected to result to industries which the artisans sent represented—their reports being confined to objects in their own trade. After considerable discussion as to the best mode of furthering the objects, the following resolution, moved by the Mayor (Mr. George Dixon), and seconded by Mr. Blews, was agreed to unanimously:—"That the proposition of the Society of Arts, of sending skilled workmen to the Paris Exhibition, to report upon the productions exhibited is approved of, and that an application be made to the members of the Chamber, and the manufacturers of the town generally, asking them to subscribe to a fund for the purpose, and also to recommend qualified men for selection by the Society of Arts." The members present gave their names as subscribers.

Mr. W. C. Aitken has also addressed a letter to Mr.

John S. Wright, Vice-President of the Birmingham Chamber of Commerce, on the subject, from which the following are extracts:—

"Should the scheme be carried out it will be the Society of Arts Working Men's Excursion to Paris, the men selected to be sent being few in number, and representing the best, the most skilful and intelligent men engaged in the industries of our country. From Birmingham a selection should be sent of artisans engaged in the leading manufactures of the town. To defray their expenses contributions are solicited, and the intention in asking the Chamber of Commerce to co-operate is to give publicity to the movement, and receive contributions from its members individually, if the Chamber, as a body, has no funds at its disposal. The reports made by the artisans sent will be published, and thus become available, not only to manufacturers, but the general public; they will tell us alike of our strength and weakness, and of our vulnerable points. Whether the ideas entertained by the manufacturers of Birmingham about the Paris Exhibition are pleasing or not matters little; but one fact is certain—they have something to learn, and they have the means of learning it by sending a few of their best men to examine and report on the contents of the Paris International Exhibition. It should be known that other countries are more alive to progress than ourselves, and to each exhibition held in this country foreign artisans have been sent by the governments under which they lived. On the authority of Dr. Lyon Playfair, we are told that Continental and other countries, except our own, since the International Exhibition of 1862, have made rapid progress, which is visible in the products of industry exhibited at Paris, contributed by other competing countries. If such, then, is the case, as I believe it really is, it is the duty of English manufacturers to take every legitimate means to acquaint themselves of what has been done and is being done; and no method can be more legitimate and proper than through the instrumentality of artisans, intelligent and skilful, who, by practical experience, are able to and will detect differences which even their employers would pass over unheeded and unnoticed.

"Under the impetus given by exhibitions, the industries of Birmingham have been improved in their ornamental features, and the processes by which the articles have been produced have been facilitated and improved. Industrial education is now the order of the day in those countries which compete with us; the results of such teachings are manifested in the works exhibited. I am glad to say that among the students attending the Midland Institute of our town there are those whose habits of observation have been so quickened, their intelligence so educated, as to render them well fitted to visit and report on the contents of the Exhibition already named.

"I view the matter as a very important one, not lightly to be passed over. Gentlemen connected with your Chamber may differ from me as to its utility or not, but I am well convinced, from personal acquaintance with the manufactures of Birmingham, that every available means of getting information should be taken advantage of; and if what is seen is new and useful, it should be applied to and in the special industry it may be supposed to benefit.

"P.S.—Appended is the probable number of artisans engaged in Birmingham trades which it might be considered advisable to send:—

"Two artisans engaged in button making. One to report on the tool making; one to report on the ornament, style, and varieties of buttons exhibited.

"Two artisans engaged in brassfounding, to report on brass and bronze casting generally; cabinet, and general brassfounding; on bells, and plumbers' brassfounding; on rolled brass, wire, sheathing, tube making; on lamps, gas fittings, and naval brassfounding. One

to report on style and ornament; the other on quality and construction.

"One artisan engaged in the manufacture of electroplate, or plated goods; to report particularly as to Russian products in silver work, and in reference to niello and enamels associated with works on the precious metals generally.

"One jeweller, to report also on gilt toys, chains, &c.

"One artisan engaged in the production of tools generally, who also has a knowledge of engineering connected with the construction of machines used in manufacturing.

"Two gunmakers.

"One japanner, acquainted with the processes of japanning, has artistic taste, and is also acquainted with the manufacture of papier maché; also to report if there are any substitutes for that material, and ascertain what they are.

"One stamper of metal, to examine as to the various processes employed in raising up thin sheet metal, as cornices and other stampings, &c.

"One steel-toy or edge-tool maker.

"One tin-plate worker, to report also on copper goods."

THE ALBERT HALL OF ARTS AND SCIENCES.

In reply to a letter in the *Times*, signed "Inquirer," Lieut.-Col. Scott, R.E., Secretary to the Provisional Committee, gives the following information in reference to this undertaking:—

"First, the Prince Consort did not state, as 'Inquirer' thinks, that 'no steps should be taken for the erection of the Hall of Arts and Sciences until the public had shown its sympathy with the proposal by subscribing £200,000,' but Her Majesty's Commissioners for the Exhibition of 1851 named £150,000 as 'the amount required to be raised by subscription before the public would be entitled to claim the benefit of the offer made by the Commissioners.'

"Secondly, as regards the popularity of the undertaking, the issue of the prospectus was commenced in the last week of November, 1865. By the end of January, 1866, £50,000 had been subscribed by the public, and in the April following this amount had risen to £100,000. The monetary panic soon afterwards induced the Provisional Committee to abstain from any further issue of the prospectus, but the success obtained in so short a time appeared to them to justify their acceptance of Messrs. Lucas's liberal offer to make up the subscription list to £150,000, and to take the contract for the works at ordinary trade prices. The Commissioners were also satisfied with these conditions, and consequently granted the site for the Hall, and guaranteed to take up sittings to the value of £50,000, in anticipation of a demand for them by the public.

"At present the subscription list stands thus:—The sum required for the undertaking is £200,000, and there has been subscribed by various persons £112,200, by Messrs. Lucas £38,000, and by Her Majesty's Commissioners £50,000; the sittings taken by Messrs. Lucas, as well as those taken by the Commissioners, being still at the command of the public.

"Thirdly, in reference to the 'curious fact' observed by 'Inquirer,' 'the total absence of the representatives of the numerous scientific societies of London' at the ceremony of laying the first stone of the Hall, I can vouch that, though his eyes failed to detect them in the vast assembly, invitations to the ceremony were accepted by the presidents of most of the leading scientific as well as artistic societies of the metropolis."

PARIS EXHIBITION.

It has been remarked, and with truth, that the British section of the exhibition is extremely unequal, some classes being fully represented, while others are sadly deficient; but the remark arises, in a great measure,

from the adoption of a false standard of comparison. Compared with other countries than France, England probably exhibits no more inequality than her neighbours. France is at home, and exhibits for her internal as well as external trade, and it is too much to expect manufacturers or merchants to take upon themselves the cost and trouble of exhibiting productions for which there is no market on the Continent. It is the business of governments and commissions to collect and show that which has only a general industrial, scientific, or artistic interest apart from commerce, and although there are some evident deficiencies, the Admiralty, the War-office, the South Kensington Museum, the Post-office, and other public establishments have done much to supply the desideratum.

Amongst the most remarkable omissions is that of the Transatlantic telegraph cable and its accessories. Since the last international exhibition no more has been achieved an act of higher practical difficulty, of more results, or one which has obtained the same amount of admiration and applause; and it is certainly one of the strangest facts connected with this exhibition that in the union of the old and new worlds by two electric cables should be totally without record on such an occasion.

Last week a short account was given of the contents of the first-class of the fifth group, mining and metallurgy; we will now visit the remaining classes of the group.

Class 41.—Forest products and the trades appertaining to them is very poorly represented, and this is not surprising, as it includes scarcely any articles of Continental demand; four exhibits of woods, veneers, and objects of wood; a collection of paper-making materials by W. H. Clarke, and one of fibres and woods of Mr. P. L. Simmonds, both of London, and illustrations of the late Capt. Fowke's experiments on timber, make up the whole list.

Class 42 is scarcely represented at all. Messrs. G. F. H. Clark and Co., of London, have, however, a good show of raw and manufactured resins and gums, and Mr. Ward a splendid case of stuffed birds.

Class 43—Agricultural products, not alimentary; this class is but little richer, there being only three exhibits of wool, one of flax, &c., four of oils and greases, one of cigars, and one of compressed fodder.

Class 44—Chemical and Pharmaceutical products. On the contrary, not only fully but admirably represented, there are more than a hundred exhibitors in this class. The chemical and pharmaceutical exhibits proper number about thirty-five, and include many of the raw products of, and some of the finest examples in the exhibition of the chemicals of commerce. There are more than a dozen exhibitors of colours, dyes, and varnishes, who represent a very important branch of manufacture.

The starch manufacture is represented by four well-known firms—Berger and Co., Colman, Orlando Jones and Co., Beckett and Sons; and the beauty of the process and the admirable manner in which the products are exhibited call forth high praise. It should be mentioned, however, that Messrs. Berger have their chief show of this article in the food court.

There are more than half a dozen exhibitions of candles, wax, spermaceti, &c., and nearly as many of soap. The amount of science which has been brought to bear of late years in the manufacture of these articles, and their enormous importance in an industrial as well as general point of view, give great interest to this portion of the British section.

Class 45—Bleaching, dyeing, printing, &c., can scarcely be said to be represented at all.

Class 46 is also weak, but there are some very fine specimens of enamelled leathers.

The food group is closely allied to the preceding, but will be found in the outer zone of the building, with entrances from the great machinery court. It is perhaps on the whole the worst represented in the British side; it is lamentably deficient.

Class 67—Cereals, &c., can scarcely be said to be presented at all, and there are two or three exhibits of *pe* which would have been more in place in the fermented liquors class.

Class 68 includes four exhibitors of biscuits.

Class 69 is a blank. This is incomprehensible; English cheese is in great esteem in France; it is to be seen in all the best shops and at most restaurants. At the two cheese exhibitions held in Paris, every English exhibitor who has contributed has received a medal, yet there is not a single English cheese in the food department. An equally extraordinary omission occurs in the next class—meat and fish; while English ham and bacon are in constant demand in Paris, and while France and several foreign countries show those articles largely, here is not one exhibitor on the British side. Again, although the question of preserved meats has been so much discussed of late, and so many important experiments have been made towards applying the surplus meat of one hemisphere to the wants of the other, there are scarcely any indications of this on the British side of the exhibition. Mr. Morton has a good show of preserved provisions; Mr. Warriner shows two joints preserved raw; Messrs. Dufaville, Sanson, and Co. show a preparation of beef tea; meat preserved in paraffine is exhibited by Mr. Redwood's Company and by Mr. Young, and the *Extractum carnis* (Læbigs) by Messrs. Allen and Hanburys, the two last-named being in the chemical class. Preserved fish is represented by one exhibitor, Mr. Austin, of Dublin, who shows a case of blotters and another of sprats.

It is not surprising that the class of vegetables and fruit is empty; the few articles of this kind which England could show are included in the general collections of the next class—Condiments and stimulants—in which salt, mustard, pickles, extracts from spices, and other matters, are fairly represented. The last class in the group, that of fermented liquors, is represented by nine or ten ale-brewers, and a very few samples of cider, vinegar, whiskey, and cordials. These last two classes are, however, very largely represented at the Exhibition, for the articles shown in them are to be found at nearly every restaurant and buffet in the Champ de Mars.

THE PARIS EXHIBITION AND INDUSTRIAL EDUCATION.

The following letter appeared in the *Times* of the 29th ult. :—

SIR,—After the distribution of prizes at the London University this year, I made some remarks on the lessons which the late war in Germany and the present Exhibition at Paris afforded to us, if we wish to hold our own with other nations in the arts of peace and war.

I quoted a speech of the President of the Civil Engineers as to the superior progress made in machinery by foreigners. I spoke from the information which I had received from a gentleman intimately acquainted with the iron trade as to the greater improvements made in the manufacture of iron in France, Belgium, Germany, and Austria. It was only from general report that I stated the little advance we have made in most departments of industry, excepting those of furniture, glass, and china.

Since then I have seen the enclosed letter from Dr. Lyon Playfair. The subject is important, and his authority is great. I have therefore obtained his permission and that of Lord Taunton to ask you to publish it.

The inquiry of 1863, to which Dr. Playfair alludes, was chiefly owing to the information given him by the Prince Consort, than whom no one was more keenly alive to the want of generally-diffused scientific instruction in this country, or more active in stimulating all classes to remedy the defect.

I am, Sir, your obedient servant,

GRANVILLE.

FROM DR. LYON PLAYFAIR.

London, May 15, 1867.

My Lord,—As you desire that I should put in writing the substance of the conversation which I had the honour of having with your Lordship this morning, I willingly comply with your request.

I have just returned from Paris, where I acted as a juror in one of the classes of the Exhibition. In this capacity I had no other opportunities than any other juror of forming a judgment in regard to it; but, having had the charge of the working of the juries in the Exhibitions of 1851 and 1862, I naturally made the acquaintance of many eminent men of different nations, and, meeting with a large number of them congregated on the International Juries in Paris, I endeavoured to gather their opinions as to the position which England occupied in this great industrial competition.

I am sorry to say that, with very few exceptions, a singular accordance of opinion prevailed that our country had shown little inventiveness and made little progress in the peaceful arts of industry since 1862. Deficient representation in some of the industries might have accounted for this judgment against us, but when we find that out of 90 classes there are scarcely a dozen in which pre-eminence is unhesitatingly awarded to us, this plea must be abandoned. My own opinion is worthy only of the confidence which might be supposed to attach to my knowledge of the chymical arts; but when I found some of our chief mechanical and civil engineers lamenting the want of progress in their industries, and pointing to the wonderful advances which other nations are making; when I found our chymical and even textile manufacturers uttering similar complaints, I naturally devoted attention to elicit their views as to the causes. So far as I could gather them by conversation, the one cause upon which there was most unanimity of conviction is that France, Prussia, Austria, Belgium, and Switzerland possess good systems of industrial education for the masters and managers of factories and workshops, and that England possesses none. A second cause was also generally, though not so universally, admitted, that we had suffered from the want of cordiality between the employers of labour and workmen, engendered by the numerous strikes, and more particularly by that rule of many Trade Unions, that men shall work upon an average ability, without giving free scope to the skill and ability which they may individually possess.

"Dumas, well known as a '*savant*,' and who, from his position as a senator of France and President of the Municipal Council, has many opportunities of forming a correct judgment, assured me that technical education had given a great impulse to the industry of France. In going through the Exhibition, whenever anything excellent in French manufacture strikes his attention, his invariable question is, 'was the manager of this establishment a pupil of the Ecole Centrale des Arts et Manufactures?' and in the great majority of cases he receives a reply in the affirmative. General Morin, so well known as the Director of the Conservatoire des Arts et Metiers, has lately sat on a commission to examine into the state of technical education in other countries, and to extend it in France, and he informed me that their recommendations were likely to be promptly and largely acted upon. I mention for your lordship's information that General Morin was of opinion that the best system for the technical education of workmen is to be found in Austria, though the higher instruction of masters and managers is better illustrated in France, Prussia, and Switzerland.

In 1863 I published a little work on "Industrial Education on the Continent," in which I pointed out that, as an inevitable result of the attention given to it abroad, and its neglect in England, other nations must advance in industry at a much greater rate than our own country. I fear that this result is already attained for many of our staple industries. But as my opinion is only that of an individual, I trust that it may accord with the objects of

the commission over which your Lordship presides to take the evidence of some of the leading jurors, many of whom had as good opportunities as myself of judging of the position which our country has taken in this great international competition.

Permit me also to make another suggestion. My inquiry of 1853 into industrial education on the Continent was a private one, and had neither official aid nor sanction, and is now antiquated. It would be important that the Government, either through your Commission or through the Committee on Education, should hold an official inquiry on this subject, and should tell the people of England authoritatively what are the means by which the great States are attaining an intellectual pre-eminence among the industrial classes, and how they are making this to bear on the rapid progress of their national industries.

My Lord, I have, &c.,
LYON PLAYFAIR.

The Right Hon. Lord Taunton.

In reply to Dr. Playfair's letter, the following communications, the first under the well-known signature of "Y," and the second by Dr. David S. Price, have likewise appeared in the *Times* :—

SIR,—In the letter of Lord Granville which you have published to-day is the following sentence :—"I spoke from the information which I had received from a gentleman intimately acquainted with the iron trade as to the greater improvements made in the manufacture of iron in France, Belgium, Germany, and Austria." Now, Sir, if this conclusion—namely, that greater improvements in the manufacture of iron have been made on the Continent than in this country, be drawn from the representation of that manufacture in the present International Exhibition in Paris, I assert that it is wholly fallacious, and for the plain and obvious reason that there is no representation properly so called of that manufacture in the French Exhibition. The reason for this is not far to seek. Our great practical metallurgists have now gained considerable experience as to the economic result of such Exhibitions to themselves, and the fact is "the thing does not pay." I know this from extensive correspondence with men who have figured prominently in that capacity at previous Exhibitions. Men engaged in the smelting and manufacture of metals are actuated by one object, and that is gain. It is only dreamers who imagine the possibility of other motives guiding the men of business in this country. Indeed, if it were otherwise, in these days of keen and constant competition, ruin would be inevitable. Were it necessary I could adduce examples of the actual pecuniary loss which has accrued to exhibitors of established reputation numerous enough to justify my assertion on this point.)

But, Sir, Lord Granville's informant does injustice to his countrymen. It may be demonstrated that nearly all the great improvements in the smelting and manufacture of iron have been made in Great Britain. Who invented puddling, whereby coal was made available for the conversion of pig-iron into malleable iron? Who invented grooved rolls, whereby the puddle-ball may, without the tedious process of hammering, be drawn out into bars? Who first succeeded in substituting coal for charcoal for the smelting of iron? Who suggested the hot blast, whereby great saving of fuel in the blast furnace is effected? Who introduced the process of casting steel? The credit of all these mighty improvements, for mighty indeed they are, is due to English and Scotch men. Such improvements are really epochs in the metallurgic industry of the world, and it is not to be expected that achievements of this magnitude will crop up in time for International Exhibitions occurring in such quick succession as of late. But, Sir, let me direct your attention to the invention of Mr. Bessemer, which dates from 1856, and which is only now acquiring its full development. That invention has already revolutionized the manufacture of iron throughout the world, and is of far greater

value to mankind than all the improvements in the manufacture of iron put together, of which France, Belgium, Germany, and Austria can boast, and Mr. Bessemer is an Englishman. It is a great invention, and if Great Britain had only produced one such in a century she would have maintained her rightful position in respect to improvements in the manufacture of iron. The products of that single invention, displayed in the Exhibition in London in 1862, may be regarded as of infinitely greater account than all the objects illustrative of iron metallurgic skill in the present exhibition in Paris, &c. I may add, than all that have been shown in all the Exhibitions which have been held. And yet, forsooth, we are beaten by the iron manufacturers of the Continent in the sphere of improvement!

In particular and subordinate departments of the manufacture of iron we are, doubtless, excelled, and this, too, where dexterity of manipulation is largely concerned, as in the rolling of girders. But let the demand for such girders be increased, and we shall produce them as well as be assured. Only a very few years ago the demand for large armour-plates was created. Who has supplied the demand? And is it not the fact that mills have been constructed in England which regularly turn out steel plates of such enormous dimensions as even in 1860 would have been considered impossible? Where else are such plates manufactured? Yet we are beaten in the manufacture of iron!

There is another point which should be noted. It is that great improvements may occur in the smelting of iron or other metals which cannot be illustrated in Exhibitions. Thus, suppose a modification in the inner form of a blast furnace, in its relative dimensions, in the composition of the charge, and in the mode of driving, as it is termed, whereby equally good pig-iron can be made cheaper than heretofore. That, Sir, you will admit, must be an important improvement. It is true a model and a few specimens of the pig-iron ticketed with the price might be sent; but they would not more adequately represent the improvement, in an Exhibition sense, than a description of it on a piece of paper. They would not appeal to the eye like a large girder, a massive ingot of steel, or an enormous armour-plate. And since 1862 we have certainly effected improvements in that direction. You will bear in mind that some weeks ago I privately placed this view of the matter before you.

In conclusion, Sir, I think I may say, without the charge of egotism, state that, like Lord Granville's informant, I also have had the opportunity during many years of carefully watching and becoming intimately acquainted with the state of the iron manufacture on the Continent of Europe as well as America, and I have no hesitation in expressing my conviction that we have no reason to be disheartened as to our position with respect to that great industry. I would neither creak nor exult. If there be cause for misgiving, it will be found in the unreasonable and mischievous machinations of paid Trades' Union agitators, who may, unhappily, succeed in diverting capital from the mills and forges of England to those of foreign countries.

I am, Sir, your obedient servant, Y.

May 29.

SIR,—In justice to British inventiveness, disparagingly alluded to in the *Times* of to-day, it is right that attention should be drawn to a very important fact—namely, that the greatest discoveries in applied chymical science of the last 20 years, and possibly of the present age, have been made in this country and by Englishmen.

To those conversant with industrial progress it will scarcely be necessary for me to state that I allude to the Bessemer process and to the aniline dyes, popularly known as the coal-tar colours. It is not for their discovery only that we are indebted to Englishmen, but for their industrial development also. At Paris these new branches of industry, the future influence of which upon trade can scarcely be foreseen, are not represented by

who have had the greatest share in their development while in the foreign courts beautiful series of designs, for the knowledge of the production of which chibitors are mainly indebted to British skill, are yielded to the greatest possible advantage.

1862 Mr. Bessemer made a magnificent exhibition at his process could effect. At Paris in 1867 he is it to let other men and many nations show how and what success they have adopted his process. No dyes are exhibited by our manufacturers, although well known that they are the first in the world. It therefore, be seen that it is very difficult for the to draw any inference as to the state of these two tant manufactures in England from what they find ited at Paris. Whether, in a national point of view, old have been right to see that our country was cor- represented in her industries, and an erroneous sion as to her skill rendered impossible, is a matter which I need not enter.

Playfair, in his letter to Lord Taunton, recom- s that further inquiries should be made into the itional systems of the Continent. Should the sug- on be adopted, I would venture to advise that an ury of equal importance for the success of industrial res should be coupled with it, and that is, as to the ing of the Patent Laws in France and Germany and elations existing between inventor and manufacturer, h it is much to be regretted are not well understood

I have the honour to be, Sir, your obedient servant,

DAVID S. PRICE.

Great George-street, Westminster, May 29.

Commerce.

THE COTTON TRADE.—Mr. Sam Mendel's circular for 1st June, says that the continued high cost of cotton, pared with the prices ruling for yarns and goods, leaves the millowner in a very unenviable and unsatisfactory position, and it is only by some decided movement in our home-trade consumption, or by a iced production, that relief can be looked for. From first-named source, there has been, within the last days, some indication of amelioration, and it is to oped that this will not only continue but increase to extent that will serve to diminish the recent and still- tinned heavy exports to India. Fortunately, the ian markets have proved to be in a healthy and strong ition, from previous short supplies and the better dition of the native population to consume the fabrics m this district. Yet it is now becoming an anxious sion as to how far supplies can continue without ducing repletion.

Colonies.

QUEENSLAND IMPORTS AND EXPORTS.—The total value the imports and exports of the colony of Queensland m and to each country during 1866 was as follows:—

	Imports.	Exports.
Great Britain....	£ 742,884	£ 321,939
Australia.....	1,711,896	1,026,377
New Zealand	—	2,541
Germany	3,921	—
India	—	3,630
Ceylon.....	—	14
Java.....	9,059	12,762
Miscellaneous..	148	253

£2,467,907 £1,366,506

he sum of £421,325, which is laid out in foreign mar- ts, chiefly English, for the supply of apparel and rapery goods, is equal to one-half of the whole annual port of wool; and the money that goes out of the ony in payment of the freight on these goods is no

inconsiderable sum. At present the colony exports the staple for the fabric of most of the clothing required, and in return it gets woollens and cottons of very inferior descriptions. Every man, woman, and child spends the sum of £9 annually in clothing.

BOWEN, A NEW SETTLEMENT IN QUEENSLAND, has now a population of about 1,600. This is another instance of the speedy rise of colonial towns, and of one which has not received an impetus from any extraneous cause, as the exports up to the present time have been confined to pastoral produce only. The value of imports in 1866 amounted to £78,200; exports, £42,437. Since the settlement of Bowen, the country to the northward has been steadily taken up by squatters, so that a new comer cannot obtain any land between this and the Gulf of Carpentaria, unless he pushes out to the westward. Notwithstanding the tropical climate, sheep and cattle do very well with ordinary care and management. The whole is being most rapidly stocked. The increase on the whole is very satisfactory. Considerable excitement exists regarding gold at Bowen just now. A small party have been at work for months past, whose object was supposed to be working of copper, which is said to exist in the neighbourhood. There has of late been a suspicion that a more valuable metal than copper has been attracting them, and this has proved to be the case, as the parties have come forward to ask a reward for the discovery of a suitable gold field, of which Bowen will be the port, the distance being about 100 miles, with a good road. Bowen has the advantage of a most superior harbour and magnificent bay, a harbour which is only surpassed in the colonies by that of Sydney. There is also the advantage of an extensive jetty, alongside of which steamers and vessels of moderate draught can now lie, and which, by a little extension, could be made available for any ordinary merchantman.

Notes.

AERONAUTICAL EXPERIMENTS IN FRANCE.—A scientific commission, including members of the French Institut, the Observatory, and the College of France, has just been formed for the purpose of drawing up a programme of experiments to be carried out with M. Nadar's great balloon, the *Géant*, and a smaller one called the *Cylindre*. Amongst the members of this commission are—MM. Regnault, president; Sainte Claire-Deville, Marie-Davy, and Sourel, of the Observatory; Laussedat, of the Ecole Polytechnic, and Renon. The Reverend Father Secchi, director of the Roman Observatory, now in Paris, and who exhibits a very ingenious electro-magnetic meteorological register, has offered his services to the commission. It is expected that the great capacity of the *Géant* will allow more complete experiments being carried out than has hitherto been possible; instruments are being prepared, and the first ascent is announced to take place from the park of the Exhibition, in a few days. It is not yet known who is to conduct the experiments.

NATIONAL MONETARY CONFERENCE.—It is said that the French Government has invited the European powers to attend a conference to be held in Paris on the 17th instant, to take into consideration the question of an international system or arrangement, and that England, Portugal, Spain, Belgium, and Switzerland have promised their co-operation.

MEETINGS FOR THE ENSUING WEEK.

MON..... R. United Service Inst., 8½. Vice-Admiral G. Elliot, "On the Hydraulic Propeller as a Motive Power for Ships."

TUES ... R. Medical and Chirurgical, 8½

Journal of the Society of Arts.

FRIDAY, JUNE 14, 1867.

Announcements by the Council.

ANNUAL CONFERENCE.

The Sixteenth Annual Conference between the Council and the Representatives of the Institutions in Union and Local Boards will be held on Wednesday next, the 19th June, at Twelve o'clock, noon. The Right Hon. HENRY AUSTIN BRUCE, M.P., will preside.

The Council will lay before the Conference the Secretary's Report of the Proceedings of the Union for the past year, and the Results of the Examinations, and the Programme of Examinations for 1868 will also be considered by the Conference.

The following suggestions of Subjects for Discussion have been received from various quarters, it being understood that in putting them forward the Council express no opinion whatever upon them:—

1. Whether the means at present available for the promotion of Primary Education are sufficient to qualify the working classes to take advantage of the Secondary Instruction offered by Institutes to Adults?
2. Whether provisions should be inserted in the Manchester Education Bill, now before Parliament, which would authorize grants to be made to Evening Schools and Classes?
3. Whether, considering the valuable results of the co-operation which the Royal Horticultural and Geographical Societies, and certain public companies, have afforded to the Society of Arts in extending the sphere of its Examinations, the like co-operation cannot be obtained from other societies and companies, especially from the Royal Agricultural and Botanical Societies?
4. Whether any additional means can be devised to induce the Institutions to form District Unions, with paid Visiting Officers, in connexion with the Society of Arts?
5. Whether additional interest in the Final Examinations might not be excited by the establishment of Special Prize Funds in the District Unions, to which Supplementary District Prizes might be added by the Society of Arts?
6. What means can be adopted by the Local Boards to secure a larger number (a) of Candidates from the Artisan Class at the Final Examinations, and (b) of Female Candidates at the Elementary and Final Examinations?
7. Whether it would be expedient to adopt, as far as possible, one specified text-book for each of the subjects in the Final Examinations?
8. Whether it would be expedient that the Society of Arts should decline to recognize an Elementary Certificate of any given year as a Pass to the Final Examinations of the same year?
9. Whether it is desirable, in the Elementary Examinations, to have one set of papers instead of two, as at

present, but with two grades of Certificates, according to the merit of the Candidates?

10. Whether, in order to secure uniformity in the Previous Examinations, the Society of Arts should furnish an Elementary Paper (distinct from the Ordinary Elementary Examinations) to meet the case of those Candidates who may not, in any previous year, have obtained Elementary Certificates?

11. Whether any steps can be taken by the Society of Arts, in order to prevail upon the Science and Art Department to grant Honorary Teachers' Certificates to those gentlemen who shall be recommended by any Public Educational Board?

12. How can the Institutions or District Unions assist the movement now being made by the Society of Arts to send selected Workmen to Examine and Report upon the Paris Exhibition?

Secretaries of Institutions and Local Boards are requested to send, immediately, the names of the Representatives appointed to attend the Conference, and early notice should be given of any other subjects which Institutions or Local Boards may desire their Representatives to introduce to the notice of the Conference.

As the subject of National Education is of peculiar interest at the present time, and several topics of great importance to the Institutions are proposed for discussion at the Conference, the Council hope that each Institution and Local Board will not fail to appoint one or more Representatives to express its views.

Secretaries of Institutions are requested to forward *at once* by book post, copies of the last Annual Reports of their Institutions.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object, and on their recommendation, have passed the following minute:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government, to facilitate the visits of skilled artisans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed, in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in

which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

The following is the list of subscriptions up to the present date:—

H.R.H. the Prince of Wales, President	..	£31	10	0
Society of Arts	..	105	0	0
Earl Granville, K.G.	..	5	0	0
Lord de L'Isle	..	10	0	0
Thomas Twining	..	2	2	0
Sir J. P. Boleau, Bart.	..	5	0	0
George Godwin, F.R.S.	..	1	1	0
Vice-Chancellor Sir W. Page Wood, F.R.S.	..	10	0	0
W. H. Bodkin (Assistant-Judge)	..	3	3	0

A circular has been issued by the Birmingham Chamber of Commerce, "earnestly asking for the co-operation of manufacturers and others, believing it to be of the highest importance that the opportunity now afforded, by which the workmen of our town may be made acquainted with the productions of continental manufacturers, should not be lost," and inviting subscriptions.

PRIZES FOR ART-WORKMEN.*

The Council of the Society of Arts hereby offer Prizes for Art-Workmanship, according to the following conditions:—

I. The works to be executed will be the property of the producers, but will be retained for exhibition, in London and elsewhere, for such length of time as the Council may think desirable.

II. The exhibitors are required to state in each case the price at which their works may be sold, or, if sold previously to exhibition, at what price they would be willing to produce a copy.

III. The awards in each class will be made, and the sums specified in each class will be paid, provided the works be considered of sufficient merit to deserve the payment; and, further, in cases of extraordinary merit additional awards will be given, accompanied with the medal of the Society.

IV. Before the award of prizes is confirmed, the candidates must be prepared to execute some piece of work sufficient to satisfy the Council of their competency.

V. *Bona-fide* Art-workmen only can receive prizes.

VI. Although great care will be taken of articles sent for exhibition, the Council will not be responsible for any accident or damage of any kind occurring at any time.

VII. Prizes may be attached to articles exhibited and sales made, and no charge will be made in respect of any such sales.

VIII. All the prizes are open to male and female competitors, and in addition, as regards Painting on Porcelain, Cameo-cutting, Engraving on Glass, Decorative Painting, and Wall Mosaics, a second set of prizes, of the same amounts, will be awarded among female competitors. If a female desire to compete in the female class only, she must declare her intention accordingly. The originals of the works prescribed may be seen at the South Kensington Museum.

IX. Any producer will be at liberty to exhibit, either in his own name or through his workmen, any work or works as specimens of good workmanship, in the various classes, provided that the work or works be accompanied with a statement of the name or names of the artisans who executed their respective portions; and if the work or works be sufficiently meritorious, extra prizes will be given to the artisans who have executed them.

X. Artizans may, if they think fit, exhibit works executed by them after other designs than those stated above, in any of the classes. Such works may contain the whole or portions of the prescribed designs, and must be of a similar style and character. Competitors must specify the class in which they exhibit. If the works be sufficiently meritorious extra prizes will be awarded.

XI. All articles for competition must be sent in to the Society's house on or before Saturday, the 21st of December, 1867, and must be delivered free of all charges. Each work sent in competition for a Prize must be marked with the Art-workman's name, or, if preferred, with a cypher, accompanied by a sealed envelope giving the name and address of the Art-workman. With the articles, a description for insertion in the catalogue should be sent. The works will be exhibited at the Society's House, and afterwards at the South Kensington Museum.

Casts may be seen at the Society of Arts, Adelphi, London, and the Schools of Art at Edinburgh, Dublin, Manchester, Glasgow, Birmingham, and Hanley in the Potteries.

* The Worshipful Company of Salters contribute £10 annually to this prize fund. The Worshipful Company of Goldsmiths contribute £15 "for the encouragement of workmen in the precious metals." Particulars of the Goldsmiths' Company's prizes are given. The North London Exhibition Prize consists of the interest of £187 7s. 3d., invested in the name of the Society of Arts, to be awarded by the Council "for the best specimens of skilled workmanship" at the Society's Exhibition of the works sent in for the prizes named above.

Photographs and rough casts in metal, &c., may be purchased at the Society of Arts, John-street, Adelphi, at the prices named.

The plaster casts of the examples in classes 2 and 4 (except has-relief 4a) may be obtained from Mr. Franchi, 15, Myddelton-street, Clerkenwell, E.C.; the other casts from Mr. D. Brucciani, Galleria dello Arti, 40, Russell-street, Covent-garden, W.C.

. The Council are happy to announce that several of the works which received first prizes in the competitions of 1863, 1864, 1865, 1866, and 1867, have been purchased by the Department of Science and Art, to be exhibited in the South Kensington Museum and the Art Schools in the United Kingdom.

FIRST DIVISION.

WORKS TO BE EXECUTED FROM PRESCRIBED DESIGNS.

For the successful rendering of the undermentioned designs in the various modes of workmanship according to the directions given in each case.

CLASS 1.—CARVING IN MARBLE, STONE, OR WOOD.

(a.) *The Human Figure*.—One prize of £15 for the best, and a second prize of £7 10s. for the next best, work executed in marble or stone, after part of a frieze of a chimney-piece, by *Donatello*, No. 5795, in the South Kensington Museum; or a relievo in terra cotta, *Amorini* supporting an entablature; original in the South Kensington Museum, No. 11,940. Dimensions—Two-thirds the size of the cast (linear).—The design may be adhered to strictly or adapted to any architectural purpose.

[Cast—Fifteen Shillings; Photograph—One Shilling.]

(b.) *Ornament*.—One prize of £10 for the best, and a second prize of £5 for the next best work, executed in marble, stone, or wood after a carved chair-back in the South Kensington Museum. Dimensions—To be two-thirds of the cast (linear).

[Cast—Twelve Shillings. Photograph—One Shilling.]

(c.) *Ornament*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed in stone, after a *Gothic bracket* in the Architectural Museum. Dimensions the same as the cast. In this design the details may be improved by the introduction of small animals, and the human head may be changed according to the taste of the art-workman.

[Cast—Ten Shillings; Photograph—One Shilling.]

(d.)—One prize of £20 for the best, and a second prize of £10 for the next best, work carved in wood after a panel in carved oak. Original in South Kensington Museum, No. 274. Dimensions—Optional.

[Photograph—Sixpence.]

(e.)—One prize of £15 for the best, and a second prize of £7 10s. for the next best, work carved in wood after the entablature of a chimney-piece carved in wood, in the South Kensington Museum, No. 85'64. Dimensions—Same size as original.

[Photograph—One Shilling.]

(f.) *Ornament*.—One prize of £10 for the best, and a second prize of £5 for the next best, work carved in wood after an *Italian picture frame* in the possession of Henry Vaughan, Esq. Dimensions optional.—This design may be adhered to strictly or adapted in such manner as the workman may think fit.

[Photograph—Two Shillings.]

(g.) *Ornament carved and gilt*.—One prize of £10 for the best, and a second prize of £5 for the next best, work

executed in wood, carved and gilt after a *Console Table* in the South Kensington Museum, No. 6,497, of the period of Louis XVI. The work to be carved roughly in wood, then to be prepared in the white by a gilder, then cut up or carved in the white by the carver, then to be gilt in mat and burnished gold. As such work may probably be executed by two persons, the prize will be apportioned as the judges may determine.

[Photograph—One Shilling.]

CLASS 2.—REPOUSÉE WORK IN ANY METAL.

(a.) *The Human Figure as a bas-relief*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after the *Martelli Bronze Mirror Case*, No. 8,717, in the South Kensington Museum—dimensions, 6½ inches diameter; or a panel in low relief, the *Virgin and Child*, in South Kensington Museum, No. 66'66. Dimensions—One-third of original.

[Cast of Mirror Case—Two Shillings; Photograph—One Shilling. Cast of Bas-relief, 3s. 6d.]

(b.) *Ornament*.—One prize of £5 for the best, and a second prize of £3 for the next best, work executed after a *tazza* in silver, date 1688, the property of Sir W. C. Trevelyan, Bart., now in the South Kensington Museum. Dimensions—The same as the model.

[Photograph—One Shilling.]

CLASS 3.—HAMMERED WORK, IN IRON, BRASS, OR COPPER.

Ornament.—One prize of £7 10s. for the best, and a second prize of £5 for the next best, work executed after a *knocker* in wrought iron, in the South Kensington Museum, No. 9,007.

If the work is executed in brass or copper, it should be rendered subject to the conditions of these metals, either as split and riveted or partly beaten from the sheet, and the awards will be made in view of these conditions. The work must not be covered with colour or any coating which masks the workmanship.

[Photograph—One Shilling and Threepence.]

CLASS 4.—CARVING IN IVORY.

(a.) *Human Figure in the round*.—One prize of £15 for the best, and a second prize of £10 for the next best, work executed after an ivory plaque of *Silenus* and *Amorini*, by *Fianningo*, No. 1,059, in the South Kensington Museum; dimensions—five inches greatest length; or after a relievo in marble, the *Virgin and Child*, No. 4,233 in the South Kensington Museum. Dimensions—To be reduced in height by one-third (linear).

[Cast of the Plaque—Two Shillings; and Photograph of the Virgin and Child—One Shilling each.]

(b.) *Ornament*.—One prize of £7 10s. for the best, and a second prize of £5 for the next best, work executed after an ivory *crozier head*, in the South Kensington Museum, No. 214'65. Dimensions—The same as the cast.

[Cast—One Shilling.]

CLASS 5.—CHASING IN BRONZE.

(a.) *The Human Figure*.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a panel in low relief, the *Virgin and Child*, in the South Kensington Museum, No. 66'66.

A rough casting in bronze, on which the chasing must be executed, will be supplied by the Society at cost price.

[Plaster Cast—Three Shillings and Sixpence.]

(b.) *Ornament*.—One prize of £10 for the best, and a

second prize of £7 10s. for the next best, work executed after a silver gilt missal cover, in the South Kensington Museum, No. 2,639.

[Photograph—One Shilling.]

CLASS 6.—ETCHING AND ENGRAVING ON METAL—NIELLO WORK.

Prizes of the Goldsmiths' Company.

Ornament.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after arabesques by Lucas Van Leyden, A.D. 1528. No. 18,968 in the South Kensington Museum. To be engraved the height of the photograph, and, if round a cup or goblet, repeated so as to be not less than nine inches in length when stretched out.

[Photograph—Sixpence.]

CLASS 7.—ENAMEL PAINTING ON COPPER OR GOLD.

(a.) *The Human Figure.*—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a panel in low relief, the Virgin and Child, in the South Kensington Museum, No. 66,666. Ground to be blue. Dimensions—Half size of original.

[Photograph—One Shilling; Cast, Three Shillings and Sixpence.]

(b.) *Ornament.*—One prize of £5 for the best, and a second prize of £3 for the next best, work executed after the back of a plate, No. 8,428, in the South Kensington Museum. Ground to be blue. Dimensions—The same as the Photograph.

[Photograph—Sixpence.]

CLASS 8.—PAINTING ON PORCELAIN.

(a.) *The Human Figure.*—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a photograph of a drawing by *Raphael*, No. 20 in the South Kensington Museum. Dimensions—The same as the Photograph. This work is to be coloured according to the taste of the painter.

[Photograph—Ninepence.]

(b.) *Ornament.*—One prize of £5 for the best, and a second prize of £3 for the next best, work executed after a photograph of ornament by *Aldegrevier*, No. 2,118 in the South Kensington Museum, and coloured according to the taste of the painter, with a gold ground. Dimensions—Double the size of the Photograph (linear).

[Photograph—Sixpence.]

N.B.—A second set of prizes of the same amount is offered to female competitors. See conditions, Section VIII.

CLASS 9.—DECORATIVE PAINTING.

(a.) *Ornament.*—One prize of £5, and a second prize of £3, for a work, executed after a photograph of ornament by *Aldegrevier*, in the South Kensington Museum, No. 2,118. Dimensions—length, 3 feet.

[Photograph—One Shilling.]

(b.) *Ornament.*—One prize of £5, and a second prize of £3, for a work, executed after a picture frame, in the South Kensington Museum, No. 7,820. Dimensions—5 feet by 3 feet 11½ inches, outside measure. The works to be executed on canvass, either with or without stretchers, in cool colours. Some lines of the mouldings may be gilt.

[Photograph—One Shilling and Sixpence.]

N.B.—A second set of prizes of the same amount is offered to female competitors. See conditions, Section VIII.

CLASS 10.—INLAID IN WOOD (MARQUETRY, &c.) IVORY OR METAL.

Ornament.—One prize of £5 for the best, and a second prize of £3 for the next best, work executed after a panel inlaid with ivory, ebony, and mother-of-pearl. The ornament to be of the same dimensions as the original, and may be applied to any object. No. 9,611 in the South Kensington Museum.

[Photograph—Sixpence.]

CLASS 11.—CAMÉO CUTTING.

(a.) *Human Head.*—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a bust of *Clytie* in the British Museum—The best copy.

[Cast of the Head—Five Shillings.]

N.B.—A second set of prizes of the same amount is offered to female competitors. See conditions, Section VII.

CLASS 12.—ENGRAVING ON GLASS.

Ornament.—One prize of £10 for the best, and a second prize of £3 for the next best, work executed after arabesques by Lucas Van Leyden, A.D. 1528. No. 18,968 in the South Kensington Museum. To be engraved the height of the engraving; and if round a glass or goblet, repeated so as not to be less than 9 inches long when stretched out.

[Photograph—Sixpence.]

N.B.—A second set of prizes of the same amount is offered to female competitors. See conditions, Section VII.

CLASS 13.—WALL MOSAICS.

Human Head.—One prize of £10 for the best, and a second prize of £7 10s. for the next best, work executed after a *Female Head* (over the lame cripple) in the archway of the "Beautiful Gate." The dimensions of the work should be regulated by the size of the tesserae proposed to be used, which size may be left to the choice of the artist. Although desirable, it is not necessary to execute the whole subject in actual mosaic. The original is at the South Kensington Museum. Tesserae of two sizes may be obtained from Messrs. Minton, Stoke-upon-Trent; Messrs. Maw and Co., Broseley, Shropshire; Messrs. Pons and Sons, Temple-street, Whitefriars, and Messrs. J. W. Rust and Co., Carlisle-street, Lambeth.

[Photograph—One Shilling.]

N.B.—A second set of prizes of the same amount is offered to female competitors. See conditions, Section VIII.

CLASS 14.—GEM ENGRAVING.

(a.) *Human Head.*—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a cameo portrait of *Savonarola*, No. 7,541 in the South Kensington Museum. Dimensions—The same as the cast.

[Cast—Sixpence.]

(b.) *Full-length Figure.*—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after a small Wedgwood medallion, No. 6,837 in the South Kensington Museum. Dimensions—The same as the cast.

[Cast—Sixpence.]

CLASS 15.—DIE SINKING.

Human Head.—One prize of £10 for the best, and a second prize of £5 for the next best, work executed after

Wood Medallion in the South Kensington Museum, 470. Dimensions—

[Photograph—Sixpence.]

CLASS 16.—GLASS BLOWING.

Ornament.—One prize of £7 10s. for the best, and a 2d prize of £5 for the next best, work executed after original in the South Kensington Museum, No. 6,785. Dimensions—As given in the wood engraving.

[Photograph—Sixpence.]

CLASS 17.—BOOKBINDING.

Bookbinding.—One prize of £7 10s. for the best and a second prize of £5 for the next best, work executed after a specimen in the South Kensington Museum, No. 16,460. The work to be bound should be some classical author of the size given. Dimensions—The same as the photograph.

[Photograph—One Shilling.]

CLASS 18.—EMBROIDERY.

Ornament.—One prize of £5 for the best, and a second of £3 for the next best, work executed, either after a *Angels* in an example in the South Kensington Museum, No. 1194, '64, or an Italian Silk in the South Kensington Museum, No. 7,468, which may be adapted to screen. Dimensions—According to the taste of the embroiderer.

[Photograph—German, Sixpence; Italian, One Shilling.]

CLASS 19.—ILLUMINATIONS.

Ornament.—One prize of £5 for the best, and a second of £3 for the next best, copy made from an Altarpiece, attributed to Giulio Clovio, in the South Kensington Museum, No. 2,958, or from a MS. border, date 50, No. 8,057, in the South Kensington Museum. Dimensions—One-half larger than the Photograph (linear).

[Photograph—Two Shillings.]

SECOND DIVISION.

CLASS 20.—WOOD CARVING.

(a.) *Human figure in the round, in alto or in bas relief. Animals or natural foliage may be used as accessories.* 1st prize of £25 and the Society's Silver Medal. 2nd prize of £15. 3rd prize of £10.

(b.) *Animal or still-life. Fruit, flowers, or natural foliage may be used as accessories.* 1st prize of £10. 2nd prize of £7 10s. 3rd prize of £5.

(c.) *Natural foliage, fruit, or flowers, or conventional ornament, in which grotesque figures or animals may form accessories, preference being given where the work is of an applied character for ordinary decorative purposes, as representing commercial value.* 1st prize of £10. 2nd prize of £7 10s. 3rd prize of £5.

(By Order)

P. LE NEVE FOSTER,
Secretary.

April, 1867.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Courtts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

EXAMINATIONS, 1867.

The following additions should be made to the List of Certificates awarded to Candidates which was given in the *Journal* of the week before last:—

- 1192—Burrell, James S., 18, Oldbury Local Board, railway carriage finisher—Arith. (1st)
- 1189—Edwards, Joseph J., 18, New Swindon M.I., clerk—Bkpg. (3d)
- 1187—Lancett, John, 18, New Swindon M.I., engine-fitter—Arith. (3d)
- 1188—Stone, Samuel, 22, New Swindon M.I., joiner—Bkpg. (3d)
- 1186—Thomson, Mary S., New Swindon M.I., milliner and dressmaker—Dom. Econ. (1st)
- 1190—Webb, George, 27, Oldbury Local Board, coach-maker—Arith. (3d)
- 1191—Whyman, John, 20, Oldbury Local Board, wagon builder—Arith. (3d).

The Second Prize in Geometry has been awarded to No. 127, Daniel Walwood, 17, Bolfast Science School, clerk.

Proceedings of the Society.

FOOD COMMITTEE.

A meeting of the Sub-Committee on Fish was held on Tuesday, 14th May:—Present, Mr. Benjamin Shaw in the chair; Mr. Caird, Mr. Ware, Mr. Michael, Professor J. Wilson, Captain Grant, and Mr. Ludford White.

Mr. GEORGE W. HART, Superintendent of the Hayling Oyster Fishery, attended on the invitation of the Committee, and laid on the table plans of the breeding and feeding ponds belonging to that company at Hayling island; also of Chichester harbour, where a portion of the foreshore had recently been acquired by the same company in order to extend their operations in oyster culture, and handed in the following statement:—

OYSTER CULTURE IN 1866-67.

It is difficult, in treating of this subject, to avoid referring to previous results obtained abroad, inasmuch as prior to June last nothing whatever had been accomplished in England in furtherance of this branch of pisciculture.

The cultivation of oysters abroad has been in three distinct and different methods, as required by as many varied local conditions.

The ancient Lake Fusaro is an example of the enclosure system; the Isle de Rhé shows us how to utilise our foreshores; and the experiments of M. Coste, at St. Brieux indicate that much may be done for the improvement of the oyster grounds in the deeper waters of the open channel.

The Lake Fusaro plan possesses many advantages over the other two, and has but one drawback—it is costly, and requires the outlay of a large capital for three years before any return is obtained; but it is undoubtedly the most certain and remunerative in the end. The successful experiments of last summer having been conducted on this plan, I shall have but little to say on the other two.

A reference to the map of England will at once show that there are on our coasts few places so well adapted for fish farming as the portion lying between Selsea-bill and Weymouth, comprising the harbours of Chichester, Emsworth, Langton, Portsmouth, Southampton, and Poole, with many other smaller inlets, and presenting at ebb tide immense expanses of mud of the very best kind for growing oysters and other molluscs.

These grounds are denuded of oysters, from the absence of any regulations or protective laws, although not many years since they abounded in natives not greatly inferior to the Whitstable or Colchester kinds.

Owing to the absence of spat, and the consequent scarcity of brood on the Essex and Kentish shores, it has of late been remunerative to companies established there to dredge in localities much more distant than those they formerly resorted to, and it is to be noted that whereas the dredgemen of the harbours above-named, although not under any regulations, of their own will abstained from the removal of spat and cultch, and returned, when caught, all oysters under two inches diameter, yet the dredgers from Whitstable and Colchester, not content with a fair share, have carried away not only brood but also every stone procurable with spat on it, and but little of the spat so obtained has been old enough for removal, and consequently died, thus causing incalculable damage, and, in fact, destruction to an important fishery here without benefitting the public in any degree, the plea speciously advanced, that although the local industry of the fishermen here was destroyed yet that the general public has been benefited by the transfer of the brood so obtained to Whitstable or Colchester, being shallow in the extreme and not borne out by the result. The consequence is that oyster-dredging in the harbours named no longer affords a living, whereas formerly the boats engaged in it were to be counted by hundreds. This being the condition of the local fisheries at the period when my attention was first directed to the subject, learning that success had attended the efforts of M. Coste to revive the French oyster fisheries, in the course of the summer of 1865 I visited the coast of France from St. Brieux to Rochelle, in order to examine and judge for myself how far his system might be applicable to our English shores.

At St. Brieux and Cancale the oyster beds were in deep water, and the cultivation was carried on by dredging, as at Whitstable, but the beds being over-worked and damaged by N.W. gales, which set in there with great violence, had become buried in the sand, and abandoned, because the few oysters remaining were insufficient to repay the labour of keeping them clean. M. Coste was unfortunate in selecting this exposed part of the coast, inasmuch as although his experiments there resulted in a wonderful success (the fascines which he had sunk over the beds averaging some 20,000 oysters each), yet the returning winter gales drove the fascines from their moorings, and once more destroyed both the brood and the parent oysters.

The system of oyster culture as pursued at the Isle de Rhé, was established nearly simultaneously with, but quite independently of, M. Coste's experiments in the Bay of St. Brieux, and was a better adaptation of means to the requirements of the locality.

The shores of this island are exposed to severe gales and heavy seas from the Bay of Biscay. M. Boëuf therefore wisely abstained from the use of fascines, and contented himself with simply providing a better arrangement of such collecting materials as were at hand, and sheltering the young from the destructive heat of the sun. This he effected by forming a series of half-tide ponds with the rocks which there strew the coast, and placing the breeding oysters under rows of these stones in the ponds so formed. Dr. Kemmerer substitutes tiles for stones, but this is the only difference.

At Arcachon the tiles yield good annual returns, but at Poole, where they were tried last summer, under the management of a French gentleman from Arcachon, the result was *nil*, and previous experiments at Southend and Herne Bay were equally unfavourable.

I thought it evident that a control of the temperature was essential to any plan for making the spat, and nearly every person engaged in the oyster trade agreed in this opinion. I determined, therefore, upon carrying out the Fusaro plan at Hayling, where I obtained on lease 900

acres of suitable mudlands, a portion of which was already bounded by a railway bank, carried across the coast for the purpose of reclamation; this ground I subsequently turned over to the South of England Oyster Company (Limited), and, acting as their manager, I have this year 30 acres under cultivation, and have laid down therein about 1,000,000 of breeding oysters, and 500 hurdles, having a total collecting surface of 100,000 square feet, or nearly 10 acres.

As there was necessarily some delay in enclosing this area, I also secured, in March, 1866, the Saltern works, on the east side of Hayling Island, consisting of an enclosure of six acres and a portion of four acres. This pond having been laid dry, and admit of the weed being removed, it was to the extent of one acre covered with sand and shingle layers, and upon the hard bottom thus obtained 50,000 oysters were placed in the month of April, together with about 80 hurdles, of 15 square feet each, placed over them horizontally, and secured by stanchions.

On the 15th June a considerable fall of spat took place, although it was not until July that any oysters were found attached to the hurdles. On the 15th the hurdles were found to be literally covered on the underside with oysterlings, the general size at the time being about $\frac{1}{16}$ inch diameter. On being removed subsequently to another part of the grounds for growing I had the numbers adhering to three hurdles ascertained, and this gave an average of 10,400 per hurdle, being at the rate of 600 per square foot of surface. Besides this satisfactory result, the shingle is everywhere covered with spat, as are also the rushes and banks of the pond, and I have no doubt whatever but that, had the whole surface of the pond been prepared with hurdles, there would have been equally well filled as the 80 laid down. The market value of the whole crop was estimated by an oyster merchant as being, at least, worth £2,000, and grown to a saleable size. These oysters have not suffered in the least from the late winter, and are growing rapidly.

I shall this year also construct collectors for the use on the Isle de Rhé system, but I think it cannot be depended upon for an annual crop, although in favourable seasons it adds greatly to the productiveness of the shores. In fact it affords simply places of attachment to the floating spat, the greater portion of which would otherwise be on unsuitable ground and therefore perish; but where natural beds exist at no great distance from the shore I am of opinion that the Isle de Rhé system will be valuable, provided the materials for the beds be at hand and obtainable at a moderate price.

I tried last year the system of fascines sunk in the Spithead Channel, but in the heavy gales they suffered the fate of those at St. Brieux.

That oyster farms on the plan of the South of England Oyster Company are beneficial to the population of the adjoining coast cannot be doubted, as at present the outlay in wages exceeds £2,000 annually, and when fully established will approximate £10,000.

There is at the present time great need of a fishery board, for the regulation of the coast fisheries. Many regulations of the Board of Trade are, in my opinion, inefficient and in many respects injurious.

The South of England Oyster Company have fitted up apparatus for hatching salt-water fish, but up to the present time I have not succeeded in obtaining fertilised ova. In a portion of their grounds, however, I bred last summer several thousands of lobsters, and I believe that this is also a branch of ocean farming which is deserving of attention.

In reply to questions by members of the Committee.

Mr. HART stated it was found necessary to enclose the whole of the breeding ponds. A bank was carried along about four feet above the water line, which was obliged to be made strong to withstand the heavy seas. There was a great difference between the temperature of the

water inside and outside the ponds—as much as from 4° to 6° every day. The average temperature at that time was about 72° . Temperature had an essential effect on the oysters, both in breeding and growing. The very severe weather did not affect the oysters so as to kill them; but the old oysters were more delicate than the young ones in this respect. He called oysters of 10 to 12 years of age old oysters, and he had them about that size for breeding. He had a Colchester native which he should say was 30 years old. The great thickness of the shell was a test of the age; but beyond a certain period there were no certain rules to go by. To a certain extent the age could be known by counting the number of rings on the upper shell. Equability of temperature was most desirable, and to obtain that there must be a body of water not less than two to three feet deep. He liked the rays of the sun to penetrate to the bottom of the ground. The bottom of the water was much warmer than the top, as he had frequently tested in going over the grounds in a boat, the difference of temperature being quite perceptible to the hand; and in a distance of a few yards there might be a difference of temperature, according to the nature of the bottom, or according as it is more or less sheltered from the wind. He took observations with the thermometer sometimes six times a day, and he almost invariably found the bottom portion of the water warmer than the top, which might to some extent be occasioned by the chilly effect of rapid evaporation. It was also the case in deep sea that the temperature of the bottom was higher than the top. He had comparative tables of the heat of the atmosphere and that of the water in the ponds, but he had not got them with him. Mr. Hart handed in the following record of readings from the thermometer in sea water in ponds 18 inches deep, from 16th June to 4th July, 1866, inclusive:—

DAY.		NIGHT.			
Max.	Min.	Max.	Min.		
60	52	54	54	16th June	Dull.
58	50	54	48	17th June	Cloudy.
58	48	52	50	18th June	Rainy.
60	52	60	52	19th June	Cloudy.
60	54	60	54	20th June	Hazy.
70	58	68	60	21st June	Clear.
70	62	70	58	22nd June	Clear.
70	62	70	60	23rd June	Clear.
70	62	68	60	24th June	Clear.
70	62	70	62	25th June	Clear.
74	64	70	62	26th June	Clear.
72	64	70	64	27th June	Thunder and heavy storm.
75	64	74	62	28th June	Thunderstorm.
76	68	74	64	29th June	Hazy.
73	64	68	50	2nd July	Overcast.
60	54	58	52	3rd July	Overcast.
60	50	59	50	4th July	Squally.

The average for the last fortnight in June being:—

For the day time..... Max. 67° ... Min. 58° ... Mean $62\frac{1}{2}^{\circ}$
For the night Max. $64\frac{1}{2}^{\circ}$... Min. $57\frac{1}{2}^{\circ}$... Mean $61\frac{1}{2}^{\circ}$

In continuation, Mr. Hart stated that the temperature of the water within the ponds was from 4° to 6° warmer than that of the external sea. On our shores there was but one species of the oyster; the difference between natives and the large coarse oyster consisting merely in the ground on which they were deposited, and their subsequent treatment. Oysters deposited on the mud would not become large like the Channel oysters; but if the natives were deposited in the channel they would become so. In some localities oysters make more rapid growth than in others; for instance, in places where there is a great deal of material to enable the oyster to make shell rapidly it will grow to a great size; whereas, if put on muddy ground, and supplied with plenty of food, and but little shell-forming material, they become fat and lazy, and they do not care to make their house larger; but on poor feeding grounds they seem to run to shell a great deal. It depends upon the supply of food. An oyster brought from the

deep-sea and placed on good feeding-ground, though it does not alter in appearance, becomes a well-fed oyster. The plan at Hayling is not to feed but to breed the oysters; to establish great breeding beds, from which it is expected a supply may be found for the feeding beds of the country. The Whitstable, the Herne Bay, and other feeding companies, we expect, will be our principal customers for young oysters, and not as competing with us. The position at Hayling, from the peculiarity of the water, is very well adapted for the production of oyster brood, especially for early brood. The facilities for forming embankments for laying down breeding oysters are also great. There is such an extent of ground there for breeding oysters as would enable us to stock to a large extent the best feeding grounds in this country?

Professor WILSON.—Are you acquainted with Poole harbour?—Yes.

I should think that was a good position, because there are hundreds of acres of mud-banks?—It is not enclosed, and you cannot do that unless you close one of the two channels. At Hayling, at Chichester, and at Langston, we have complete facilities for enclosing the grounds. The feeding grounds at the mouth of the Thames are said to owe their special value to the amount of London sewage deposited there.

Mr. CAIRD.—With regard to the Fusaro plan, where had it its origin?

Mr. HART.—At Fusaro, the old Avernus, a little distance from Naples. It was used as an oyster pond formerly, and has been so since. The plan adopted there is that of piling up stones on the muddy bottom, which is very offensive black-looking mud, and when stirred up the stench is unbearable. Stones are placed upon the mud, and the oysters upon the stones. Piles are driven round the ponds and fascines are hung upon them by strings suspended vertically. The lake communicates with the sea by means of a small canal. The tide at Fusaro is very little, and the canal is about two miles long. I am not aware what is the depth of water in the pond. The temperature would probably be higher than anything ever occurring at Hayling. By means of an enclosure from the sea, and the power of admitting the tide when thought proper, we can to a great extent in summer time govern the temperature of the breeding-beds, and this is most essential.

Do you suppose, generally speaking, on the coast of England the temperature is sufficient for the production of the spat?—I cannot say what the temperature is, but I think so.

The difference between your system and the natural process is this—that in the open sea, the temperature is not very high, and the tides flowing out and in daily, renders it impossible to regulate the temperature, so that the spat either may not be produced, or may be lost when produced?—That is one of the things; but the spat goes backwards and forwards with the tide. But in our ponds we can regulate the temperature to a great extent, and to a great extent control it during the spatting season. A succession of cold nights would be injurious to us. Last summer the temperature was not lower than $62\frac{1}{2}^{\circ}$ in the middle of the day and $61\frac{1}{2}^{\circ}$ at night, and this continued for fourteen days together, and that was at the time when the spat was coming on. There was no spat in Chichester Harbour last year, except in our beds. By regulating the temperature we insured spat, while there was no natural spat outside. In a good season the spat is produced in such enormous quantity that, if preserved, it would be sufficient to stock the feeding-beds of the country for six or seven years in succession, but after many years, when there has been a want of spat the beds become dirty, because it does not pay to dredge, and when the spat comes the ground is in a bad state for it, and the spat is sacrificed. Last year the first experiment was tried. We had about four acres of ponds, and about one acre of shore for laying oyster

ova. We had eighty hurdles, and 50,000 breeding oysters. The success of last year was so decided that we have greatly extended our operations this year. We shall have 10 acres of collectors instead of 1,200 feet; and 20 acres of shingle instead of one; and a million of oysters instead of 50,000. Our supply is dredged off the French coast, from ground which it was open for nation to fish upon.

After you have completely established, should you be so fortunate as to do so, breeding beds of this kind, it is not necessary to recruit the ground at the same rate that you have been doing; the mother oysters will continue to breed?—I should myself prefer to change the breeding stock every year.

What would you do with those which have bred?—Send them to the London market. We can fatten them equal to the Shorehams, but not so as to be comparable with the natives. The Shorehams are deep-sea oysters, and are laid upon shore beds to fatten.

You would not keep the brood oysters after one season?—No; they get poor in winter.

When would they be ready for the market?—Before Christmas the same year, but they would have to be sent to other beds for the purpose.

Then you prepare ground for a new stock of mother oysters from the deep sea?—Yes, every year. We find that the change of ground is most beneficial to the oysters, and it is that which constitutes the Whitstable working. They dredge the oysters from one bed and shift them to another piece, though it may not be far off. It is that which gives the oysters their good flavour, and causes them to fatten so rapidly. I fancy the reason why our spawn comes so early is that we bring the oysters out of deep water and put them in shallow.

Your plan involves a fresh supply of parent oysters from the deep sea every year of about 2½ millions?—I think it is desirable to have them.

In your future operations you do not anticipate the necessity of entirely stocking the beds with breeding oysters from the deep sea?—No.

Have you formed any opinion as to whether the oyster is hermaphrodite, or male and female?—I believe both the sexual organs are present, but whether milt will fertilise the ova of the same animal I cannot say. I find in May nothing alive in the oyster but spermatozoa; but that both organs exist I am sure, because I find spermatozoa in every oyster, but not always ova. I think we may be able to select the oysters which are to be kept for brood, and send away another portion for feeding or breeding stock. I think as soon as the grounds are well filled there will always be sufficient left at the bottom of the ponds to keep up the spat. After the grounds are matured we do not think there will be much call by us upon the beds of the sea. The oyster commences to breed about two years old, and small oysters of that summer will be fit to send off to the feeding grounds by Christmas, but we shall probably keep them till next summer. They are sold at so much per bushel or tub. We buy the oysters from the deep sea beds by the bushel. We have been paying less this year than we did last. Last year we paid 7s., this year we paid only 6s. The oyster brood of last year will be fit for the London market in about two years.

The CHAIRMAN, reverting to the paper handed in by Mr. Hart, and read at the commencement of the sitting, said there was at the latter part of it reference made to a matter on which the Committee might be able to take some action. That was with respect to the regulation of the Board of Trade in relation to the coast oyster fisheries, on which Mr. Hart expressed himself that some alterations were required in the interests of those fisheries. They had listened to what Mr. Hart had stated to the Committee, but it did not indicate any course of action. If prejudicial regulations required to be removed, he apprehended that was something to which the Committee could practically turn their atten-

tion. He would, in the first instance, ask Mr. Hart in what way he conceived the regulations of the Board of Trade operated injuriously to the oyster fishery in the country?

Mr. HART replied that at present dredging is permitted in the month of September, which, he said, was exceedingly wrong; and not only that, but they authorised dredging to be continued the whole summer through English waters.

Mr. CAIRD said it was pressed upon the Fishery Commissioners the propriety of curtailing the time in month at the end of the season, and adding one month at the beginning. The reasons urged for this were two—first, that as the oysters did not generally begin to spawn till the month of May, it would be an immense advantage to the fishermen to go to the deep-sea to fish in quiet water. Then, again, it was stated that in the month of September the oysters had not recovered from spawning, and were out of condition; for those reasons the changes were made. It was no doubt highly objectionable that oysters should be taken at a time when they were out of condition; but the young brood would not be destroyed by dredging in September.

Mr. HART apprehended that dredging at that period could not be carried out without injury from the dredge to the young spat. With regard to the damage done by the Whitstable and Colchester fishermen being allowed to procure spat from anywhere they choose, he had something to say on that point when they came to it. He spoke in the interest of the local fishermen. The Whitstable people especially were greatly given to overstocking the beds to the extent of carrying off the spat and culch, and wholly destroying the ground, and there was no power to prevent them doing this vast amount of injury to the deep-sea beds. The company with which he was connected, Mr. Hart added, had applied to the Board of Trade to give them a channel which was now used as a dredging ground, and they offered to stock the water inside the Isle of Wight, provided the Board of Trade would appoint a conservancy board to manage it. The company offered to provide the spat, and stock the ground for the benefit of the local fishermen; but of course the Whitstable people must be precluded from coming to dredge there. At the commencement of the season they came 50 or 60 sail strong and took away everything they could get, and left nothing to breed from. The local fishermen would, for their own sake, work the ground properly and keep it well stocked. In reply to further questions, Mr. Hart stated that he had seen the green coloured oysters met with in France, which he considered to be the result of local circumstances. He said he could make oysters green in a fortnight; it was a mere matter of the ground on which they were placed.

Mr. CAIRD remarked that in the neighbourhood of Malden, in Essex, a peculiar green coloured oyster was produced, which for years past had been sent to the French markets.

Mr. HART stated that there had been a great quantity of the green weed, which grew immensely in the ponds under his superintendence, which at first affected the colour of the oysters, imparting a green colour to the beard; but as the weed in question was removed, the oysters became of a proper colour. Blanket weed was the local name given to the plant of which he spoke.

Mr. CAIRD remarked that a green coloured description of oyster was found in the shallow waters of the Mediterranean.

The following information has been received through the courtesy of Lord Stanley, Secretary of State for Foreign affairs:—

BELGIAN LAW AGAINST ADULTERATION OF FOOD.

Those who have adulterated, or caused to be adulterated, provisions, or drinks, or any kind of alimentary

substances, intended for sale, shall be punished by an imprisonment of from eight days to a year, and a fine of from 50 to 1,000 francs, or one of these penalties only.

The persons punishable under the preceding article are—1st. Those who sell, or expose for sale, provisions, drinks, or alimentary substances of any kind, knowing them to be adulterated. 2nd. Those who, by placards, written or printed, published, sold, or distributed, shall maliciously give instructions for facilitating or aiding in the adulteration of food and drinks.

Imprisonment from eight days to six months, or a fine from 26 to 500 francs, or one of these penalties only, is enacted against those who have in their warehouse, shop, or any other place, drinks, provisions, or alimentary substances, intended for sale, knowing them to be adulterated.

In certain cases, when the accused shall be condemned to an imprisonment of more than six months, he shall be deprived of his license, and will not be able to obtain another during the term of his imprisonment. The court can always direct that the judgment shall be posted in places where it orders, and inserted, either entire or in extract, in such newspapers as they may direct, at the expense of the convicted.

The provisions of the law will be applied without prejudice to heavier punishments given by the Code Pénal, or by special laws.

Those who shall, without criminal intent (provided for under the foregoing law), sell, or expose for sale, adulterated drinks, provisions, or alimentary substances, shall be punished according to articles 475 and 476 of the Code Pénal. In case of a fresh offence, the penalty of imprisonment for five days at most can be pronounced.

In fining, the court and tribunals can order that, in default of payment after two months from the date of the judgment, whether after a hearing, or notice, or by default, this fine may be changed into imprisonment, not exceeding the term of a year, in the cases above provided for, or by a simple police imprisonment, not exceeding the term of seven days, in cases named in the preceding article. The condemned can be always released on paying the fine.

With regard to the condemnation in costs pronounced for the benefit of the state, the duration of imprisonment shall be fixed by the judgment or decree, which cannot be less than eight days, nor more than one year or one month, according to the nature of the offence. Nevertheless the convicted, who can prove their insolvency according to the Criminal Code, can be liberated after having undergone seven days' imprisonment, when the expenses shall not exceed 25 francs. Imprisonment is not carried out against those convicts who have attained their 70th year.

Adulterated provisions, drinks, or alimentary substances which are found in the possession of the culprit shall be seized and confiscated. If they can be used for food, they shall be handed over to the charitable institutions of the Commune where the crime has been committed. If not they must be destroyed.

The penalties can be applied cumulatively or separately.

When any extenuating circumstances exist in favour of the accused, the penalty of imprisonment and fine pronounced under the present law can be reduced respectively below 8 days, or below 26 francs, without their being simple police cases.

REGULATIONS FOR THE SALE OF BUTTER IN THE CITY OF BRUSSELS.

Two experts are appointed for the examination of butter destined for sale or the consumption of the inhabitants. These experts are named by the Conseil Communal; they enter on their duties after having taken an oath to fulfil them faithfully.

The local police, accompanied by the experts, make frequent visits to the markets, and to the dealers in all

public places where this commodity is sold. Butter for sale cannot be withheld from being inspected by the experts.

Butter supposed to be adulterated shall be provisionally seized, and submitted to an analysis by the city chemist. His report, combined with that of the experts, shall be transmitted, within three days from the date of the seizure, to the chief Commissioner of Police, who shall institute, if there be reason, the prosecution authorised by law.

At the wholesale market, butter can neither be sold nor exposed for sale, if it has not been previously submitted to the examination of the experts. Butter of the first quality will be, if required by the dealer, stamped by the expert with a wooden stamp, adopted by the Burgomaster and Aldermen.

Butter at the wholesale market is divided into three qualities, the first of which comprehends butter of the best quality stamped; the second, every kind of butter not mixed and not stamped. Butter described as mixed butter forms the third quality; a special mark is affixed to this butter.

Dealers are forbidden to assume at the wholesale market any other quality than that assigned them by the experts; they may neither alter nor efface the marks indicating the quality of butter before they deliver at the houses of their customers.

The Burgomaster and Aldermen shall deliver to the carriers of butter whom they consider most worthy of the confidence of the public, a plate with a number. These men must, in every respect, conform to the police regulations.

Besides the prosecution of delinquents for adulterating or selling adulterated butter, the infraction of the foregoing rules may be punished by a fine from one to fifteen francs, and an imprisonment of one to five days, cumulatively or separately, according to the gravity of the offence.

WEIGHTS AND MEASURES.—GENERAL REGULATIONS.

The decimal metrical system of weights and measures established by the law of August 21, 1816, continues to be applied in Belgium. The proper standards are kept.

The verification of weights and measures is duly provided for, as is also the supervision of weights and measures. The excise clerk specially commissioned for that purpose inquires into, with the assistance of the *employés* of the registry, and the officers of judicial police, any offences against the regulations for weights and measures. The verifiers and assistant verifiers have the duty of also ascertaining offences against the law; they take an oath before the president of the tribunal of their department. The official report of these functionaries is received as true till the contrary is proved. Persons in business where weights and measures are used are liable to the visits of these functionaries as long as their places are open.

Other places not open to the public are also subject to these visits after sunrise and before sunset; but the clerk of the excise and the verifiers can only enter these in the presence of a commissioner of police, or a member of the Communal Administration; and the procès verbal shall, in that case, be signed by him in the presence of him who makes it. The produce of the fines derived from false weights and measures shall be divided among those making the procès verbal and the state. Nevertheless, when the prosecution takes place by the public officers the fine goes entirely to the treasury.

As regards penalties—1st. A fine of 20 to 25 francs is imposed on those who possess false weights, measures, or false weighing machines. 2nd. A fine of 10 to 20 francs on those who refuse to admit the visit of the proper officers. Those who possess or employ weights and measures prohibited by article 4 of the present law. A fine of from 5 to 15 francs will be imposed on those

who possess or employ weights, measures, casks, weighing machines, not marked in the prescribed manner.

The punishment of imprisonment is from one to seven days, according to circumstances.

In default of payment of the fine, the judge may order imprisonment not exceeding seven days, the prisoner to be released on payment of the fine.

When a person is condemned in costs for the benefit of the State, the duration of his imprisonment shall be fixed by the judgment, and must not be less than eight days or exceed one month; but if insolvent, the condemned, on showing his insolvency, according to law, will be liberated after seven days' imprisonment. Persons of seventy years and upwards cannot be imprisoned. In addition to this, all false weights, measures, and instruments will be seized, confiscated, and broken, but instruments which show no other irregularity beyond the loss of their verification mark will be simply seized, and restored after judgment, as also casks which do not bear the prescribed mark. Casks bearing false indications as to their contents are treated in the same way as false measures.

THE PARIS EXHIBITION.

Having indicated what we believe to be some of the most important facts to be remarked in connection with the machinery, hardware, and other leading branches of industry on the British side of the exhibition, and we last week pointed out some of the most glaring deficiencies, to-day we select some classes in which Great Britain is avowedly well represented.

The horological department of the English section forms one of the most attractive of its classes, and the admiration of well-informed foreigners is loudly expressed. Without waiting for the verdicts of the jury, it may fearlessly be affirmed that English chronometers, clocks, and watches have achieved a great triumph. In the case of marine chronometers, the triumph is perhaps more decided than in any other branch of the trade, and this fact is all the more important when we consider the very high place which the chronometer manufacture fills, both as regards scientific adaptation and manual skill. The show of chronometers is at once large and select. The exhibitors include Mr. C. Frodsham, who is also a juror, Messrs. Parkinson and Frodsham, Dent, Blackie, Johansen, Kullberg, and Mercer, all of London, and Mr. Sewell of Liverpool, and it is not too much to say that England need fear no rival in this important branch of the trade.

In pocket chronometers, chronographs, and first-class watches of all kinds the show on the British side is magnificent; and the many new adaptations adopted for the improvement or the preservation of the mechanism prove that in this manufacture at any rate there is positive progress, scientific as well as industrial. High-class watches are exhibited by Messrs. Walker and Sons, Adams and Sons, Nicole and Cupt, Vivier, E. White, and by nearly all the chronometer makers above mentioned.

For excellent economical watches the English show is quite as remarkable as for the superior class just referred to; Messrs. Walker and Sons' watches for railway guards, engineers, travellers, and others, supply an example of good work at moderate cost. In the ornamental articles in the class the progress is as marked as in the rest; the decorations are generally in good taste and faultless in execution; Messrs. Dent, E. White, Walker and Sons, and Sewell show many examples of engraved and enamelled watches.

Mr. E. White exhibits specimens of chronometers and watches specially adapted to Turkey, India, and China, which may be taken as a type of the superior export trade of Great Britain. Messrs. Walker's Indian regulators may also be quoted as examples of another important branch of the trade; and Mr. G. J. Oram

furnishes a good collection of watches for the general export trade.

In large clocks, Messrs. Dent exhibit a model, with Mr. Denison's escapement, of beautiful workmanship; and Mr. Benson shows a fine turret clock, capable of carrying hands for a dial of 15 to 18 feet in diameter, and also a smaller specimen.

It is certainly not in the class of horology that we must look for evidences of England's decline. Nor must we seek it amongst the jewellers, whose productions form another of the highly-attractive portions of the English section, and are universally admitted to show a remarkable improvement in taste, with undiminished excellence of workmanship. This is so evident that no one questions it. One exhibitor in this class, Mr. Phillips, has taken up a peculiar branch, namely, the reproduction and application of the forms of ancient jewellery, Egyptian, Persian, Etruscan, Greek, and Roman. He also shows some jewelled and enamelled mountings of cut rock crystal and other precious stones.

Let us take another class, of a totally different character to both the preceding—the only bond between the three being that art enters more or less into them all—and visit the English ceramic court. In the class of brown stone ware, and especially in the important sections of chemical and sanitary pottery, Vauxhall stands alone, the size, regularity of form, and solidity both of body and glass of the worms, bottles, acid jars, pipe joints, stop-cocks, and many other highly-important articles exhibit great advance, and leave all competitors further than ever in the rear.

In other branches of this class of industry England has a remarkably fine show, and the evidences of progress are noticed at every step. The substance of the porcelain and earthenware is finer and more solid, the glaze more even, the colours more brilliant and pure than ever. The forms, as well as the decorations of table and other household ware, become more elegant at each exhibition.

But it is in the ornamental pottery that the greatest progress is observable. Messrs. Minton have long been famous for their majolica ware, and the show which they make upon the present occasion certainly surpasses in quality any previous exhibition of theirs, while they present some important novelties. Amongst the latter, one of the most striking is the mixture of what is called *parian* enamelled with celadon coloured china; there is a case full of examples of this new style. In some instances the ground is of celadon, with opaque and semi-transparent ornaments of *parian*; in others the celadon is laid upon a *parian* ground, either solid or in thin transparent films that produce a very delicate effect, while in others the two materials are joined without being absolutely mingled. In one case the junction is made in a peculiar manner: the body of a vase is formed of china and painted, while the other portions are of *parian*, which will not take colours. Amongst Messrs. Minton's other novelties are some imitations of *Limoges grisaille* enamel ware, including a beautiful vase by an artist named Stevens; and specimens of stone china painted in solid and brilliant colours, imitating the famous old *cloisonné* enamels of China.

Messrs. Copeland and Son exhibit, amongst other objects, a china vase, five feet high and of great purity of form and body, with flowers finely painted by Mr. Hurten, the neck and foot of delicate green and gold, some jardinières, and a pair of smaller and very beautiful vases, decorated by the same artist; a splendid dessert service belonging to the Prince of Wales, and another with pierced edges and painted fruit; an ornamental set, decorated in a peculiar manner, in purple monochrome; dinner and other services with fillets and cyphers; some handsome painted earthenware panels for decoration; several specimens of improved jewelled ware, in the form of Veralum bottles and vases; specimens of a happy application of *parian* for the supports of centre pieces of dessert services; and a

curiosity in the way of gold decoration. In this case the gold is not laid on the surface of the ware, but is actually inserted, in the form of scales, with the surface level with that of the ware, and when the ware is completely finished the gold is engraved by hand.

Messrs. Wedgwood have a very fine show of their peculiar ware, known in general by their name, but in the trade as jasper ware. Many reproductions of Flaxman's charming designs, and other works conceived in the same spirit, as well as some novel applications of cameos and panels in a similar style. But besides this, they have a complete novelty, which has attracted great attention, a new kind of ornamental ware; the body is fine faience, and the decorations are painted, with great skill, by Mr. Lessore, after whom this new faience is christened. The subjects consist of landscape, animals, and flowers—some drawn from La Fontaine's fables and the works of other authors, and others original. This ware has found purchasers in the highest quarters. The Emperor of the French is stated to be one of Messrs. Wedgwood's customers, and the other great English potters have also been largely patronized in the same manner. Another of Messrs. Wedgwood's novelties which may be mentioned, is a service, decorated with designs from Chinese MSS., brilliantly painted by Mrs. Brownaword.

These are not the only classes in the group to which they belong in which England exhibits great excellence, and very marked progress, but these must be noticed in a future number.

The number of visitors to the Exhibition, for the time of year, surpasses all precedent and expectation; the receipts have exceeded £3,900 in one day, and the numbers, although fluctuating, are always large, yet the building is rarely crowded, except when there is a sudden shower of rain. One cause of this is the mass of attractions out of doors, and another, which deserves special notice, the great facility of ingress and egress by the radial avenues, or streets, as they are called, which connect the inner garden with the park; when visitors feel somewhat fatigued, and catch a glimpse of trees and grass through one of these openings, they naturally make for the open air, greatly to their own comfort, as well as that of others, and return refreshed to the study of the Exhibition itself.

THE PARIS EXHIBITION AND TECHNICAL EDUCATION.

The following letters have been addressed to the Editor of the *Times* :—

SIR, —The correspondence which you publish on this subject involves some collateral issues which seem calculated to divert the attention from the main subject under the heading which I have put to my letter. I am not disposed either to discuss or to admit the supposition that England has been at all points distanced by France and Germany. The important point, as it presents itself to my mind, is, whether we are not allowing them to attain a very marked general advantage in one important respect—namely, permitting them, by our neglect, to surpass us in their theoretical knowledge of the materials which they use, and in the best methods of working them up, whether derived from special acquaintance with the particular art, or from general instruction in mechanism and combination of materials. If this be so—and I believe it is—no man who values his time will care to discuss whether we can compete with the foreigner notwithstanding. We must surely compete upon better terms if we can escape the disadvantage.

I have just revisited Paris after twenty-two years' absence from it. During the past twenty years I have been officially connected with education in England, and have for some time been engaged in the actual teaching of what the French call a special application. I thus had strongly impressed upon me both the alteration

which has taken place here since 1846, and the comparative difference between the two countries; and I have thought you might like that I should give you my impressions.

In the first place, I find that the French have made immense advances in the application of small mechanism to the necessities of every-day life, and that they are now as far in advance of the English in this respect as we were beyond them in 1846. This is only one indication among many that there has been a general advance of this kind of knowledge; but I find something more in my observation of the people. I find them better disciplined, more attentive to small things, more alive to the necessity of applying their intelligence to detail, and better taught how to apply it. In the higher respect of pure mechanism I find that their detail occasionally errs in being too elaborate, but never from want of calculation or neglect of care. I find also that they are far more accustomed to submit, not only their main intention, but also their subordinate detail, to the test of exact or approximate numerical calculation, than is at all common with any but a few of our best mechanical designers. Lastly, I find that this is the result of a systematic plan of technical education pursued in France for now three-quarters of a century, in spite of war and revolution. This system is now bearing year after year increased fruit, and there is scarcely a large business in France in which the whole of the scientific knowledge bearing, even collaterally, on the subject is not fairly understood and mastered by those directly concerned in the business.

In England it is not a common thing to find theoretical knowledge combined with practical work. Practical mathematics are especially rare. There is nothing like the familiar habit which one sees every day exemplified here of working out every detail of mechanism or a chymical process by actual calculation and working diagrams. Some will say, doubtless, that we English do not need all this; for it is only the educated man who is capable of seeing how far his knowledge is deficient. But I have yet to learn that there is such a difference between man and man that any nation can afford to throw away the advantage of superior information.

Yet that is just what we shall do unless we take up vigorously and earnestly the work of technical instruction. There is a time in the military history of nations when individual prowess is sufficient to procure national supremacy; and there is a time in industrial progress when isolated energy and perseverance will secure manufacturing predominance. But there is a time in both when discipline and systematic training become necessary for the people to secure their position among nations; and that time, as I think, is now at hand for us.

It is quite true that our Universities teach mathematics in a way with which I should be the last to find fault, considering the purposes for which they are intended. But that purpose is wholly apart from the practical applications needed by the middle classes, and it is diverging more and more from what is chiefly useful to them. It is geometry rather than Euclid that they want, and it is mensuration rather than mathematical logic, which is of use to them. The middle classes cannot afford to spend their adolescence in an education which only opens the gate of knowledge; their instruction must be practical from the first, and there is no real impossibility in combining that accuracy of deduction, without which mathematics cease to be an exact science, with practical rather than logical applications.

I have no right to constitute myself the exponent of Lord Granville and Dr. Lyon Playfair, but as I read their letters their main object seemed to me to be to call attention to the disadvantages under which we lay from this want, which unquestionably exists among us, of technical instruction, and to the serious consequences which had already accrued, and were likely to be increasingly felt from this cause. It is putting the ques-

tion on a false issue to answer them as if their object were a mere comparison of our existing manufactures. In so far as my own limited experience is concerned, both of men and of mechanism, of students and teachers, I do not think that they have exaggerated in any way the danger.

At the same time I have no fears for our country, provided we really, as a nation, recognize the need, and apply ourselves to the remedy. But it must not be supposed that we have a light task before us. Our teachers, as well as our schools, have yet to be produced.

I have, &c.,

CHARLES W. MERRIFIELD, Principal of the
School of Naval Architecture.

Paris.

SIR,—The expression, "technical education," has recently appeared in your columns, but without any precise definition. What is "technical education?" Let me try to answer that question by giving an illustration drawn from a particular department of manufacturing art to which I have especially devoted my attention during the last five-and-twenty years, and during sixteen of which I have been engaged in the work of instruction connected with that department. It is necessary that I should make this statement, because certain of your correspondents on the subject have sought to gain the ear of the public by announcing their own more limited experience as teachers of what they designate "a special application." In the extraction of iron from its ores a series of processes is resorted to with which many of your readers are familiar. First comes that of smelting, which consists in exposing the ore in admixture, say, with limestone, to a high temperature in a gigantic furnace urged by powerful blasts of air injected near the bottom. The fuel may be charcoal, coke, or coal, and in every case it is in direct contact with the ore and limestone. The products are what is known as pig or cast iron, and a more or less glass-like substance, known as slag or blast-furnace cinder. This cast iron is not pure iron, but is compounded of pure iron and carbon, with the addition, it may be, of silicon, sulphur, phosphorus, manganese, and other matters. Next follows the process of puddling, whereby this easily fusible non-malleable, non-ductile, unweldable metal is converted into the difficultly fusible, malleable, ductile, weldable metal wrought iron, or that variety of iron in commerce which most closely approximates to the chemically pure metal; or, in the case of suitable kinds of pig iron, the Bessemer process may be adopted as a substitute. Lastly come the processes by which steel may be derived, either directly or indirectly, from cast iron. Now, Sir, all the processes which I have thus briefly referred to may be, and are, successfully carried on by men wholly ignorant of the chymical differences between wrought iron, steel, and cast iron, and of the chymical phenomena which occur in those processes. Such men have a merely empirical knowledge of the metallurgy of iron, acquired by tradition and the education of both eye and hand. But the man who knows the essential nature of wrought iron, steel, and cast iron, and who is acquainted with the chymical changes that are made in the process of smelting, and in the other consecutive processes, has a scientific knowledge of the subject. It is only this latter branch—that is, the principles of this manufacturing art—that can form the subject of instruction at metallurgical or mining schools. The knowledge of the other, or practical branch, can only be acquired at iron-works. That a knowledge of the principles of this art may lead to improvement and to great practical results could easily be demonstrated by numerous examples—examples, indeed, so numerous, that I would undertake to fill six columns of the *Times* with the record of them. Let it not be supposed that no technical instruction has been provided in England in the great subject of metallurgy and the

kindred arts, and instruction, too, provided by the Government. Not many years ago, notwithstanding the prominent position which Great Britain then held among the iron-producing nations of the world, scarcely a chymist could be found in any ironwork in the kingdom, and such a thing as an analysis of an iron ore or of iron was hardly ever thought of. What is the fact now? Why, the absence of an expert chymist from a great ironwork is the exception, and not the rule. I could supply you with the names of able chymists thus scattered through our ironworks. And what is true of iron-work is equally true of other branches of practical metallurgy. During the last few years I have had the opportunity of seeing the examination papers on metallurgy of working men, sent to the Science and Art Department at South Kensington, from various parts of the United Kingdom, and I say with confidence that at least in that branch much progress has been made in the diffusion of "technical education." The press, also, has done, and is doing, great and useful work in this direction. I am personally acquainted with many of our chief metallurgical works and have had ample opportunities of conversing with the working men they employ, and I have been delighted to observe their desire for knowledge concerning the principles of their art, and on many occasions how much knowledge of those principles they had obtained. It is untrue to allege that there is no technical education in England, and those who made the allegation ought to have known better. I speak of what I know respecting one great branch of manufacturing industry in this country, and I am prepared to maintain what I here assert. Do not let me be misunderstood. The value of what is called "technical education," or education specially directed to manufacturing art, cannot be overestimated. The Government has taken the initiative in this matter, and the nation has already begun to reap the advantage, and, I might say, other nations too, for I could give a list of men from the continent of Europe, from Australia, from India, from South America, and from the United States, who have received special technical education in England—nay, even in London. Let us not only go on as we have been going on during the last 15 years, but redouble our efforts if necessary. There is no ground for alarm. We cannot hope to excel in all things. It is probably not expedient that we should. There are other people in the world as wise and energetic as ourselves. But, so far as our national resources will permit, there need be no apprehension of our being beaten at least in practical metallurgy by the rest of the world.

I am, Sir, your obedient servant,

June 12.

Y.

Fine Arts.

RESTORATION OF ANCIENT EDIFICES IN PARIS.—Visitors to Paris this year will find several interesting buildings recently restored or now under hand. The ancient priory of Saint Martin des Champs, occupied by the Conservatoire des Arts et Metiers, has been many years in the hands of the restorer, and is now approaching completion; the priory church has long been occupied by machinery in motion, but the apse, which is very fine, has only recently been restored. The outside of the church, like most cathedrals and other ecclesiastical edifices on the Continent, is masked by a row of wretched tenements, which are now being removed. Visitors who are not acquainted with Paris must not omit to visit the ancient refectory of the priory, a very remarkable building of the 13th century, attributed to Pierre de Montreuil, which stands parallel to, and not far from, the inner wall of the church, and is now the library of the Conservatoire; it is a curious, long, narrow structure, with a row of columns up the centre. The restorations of Notre Dame are now entirely terminated, with the

of a portion of the side chapels and some sub-work. The whole of the main structure is and the general effect is excellent. The upper he beautiful *chapelle* of Saint Louis was com-restored and embellished some years ago, and the apel is now in the hands of the restorers, and es termination. The city of Paris is occupied restoration of the *Hôtel Carnavalet*, which is to contain the museum of the antiquities of The opening up of new streets not far from the markets, has laid bare one of the most remark-uments in Paris, namely, the tower of the residence of the Dukes of Burgundy, built by int Peur, which is fortunately in an excellent preservation. This will be a remarkable addition rchitectural antiquities of Paris, for it has been ely masked for a long period by houses, and lost at earnest students; it is an admirable specimen Burgundian architecture which is seen in such orms at Dijon, the capital of the once powerful f Burgundy. The city of Paris has also recently d the *Hôtel de Sens*, occupied in the middle ages Kings of France and the Archbishops of Sens, about to cause it to be restored.

IBITION OF WORKS OF ART AT BORDEAUX.—atalogue of this exhibition contains 668 entries, ng works by Diaz, Landelle, Théodore Rousseau, veral other painters of eminence. The municipal l purchased two works by M. Dauzats and M. y, both natives of Bordeaux, for the museum of wn, for 6,000 francs; the society directing the tion made purchases to the extent of 22,500 , and private amateurs to the amount of 35,000 , making altogether a total of £2,540.

Manufactures.

IBIO'S ARTIFICIALLY PREPARED MILK.—This cele-d chemist has made a communication to the French emy of Sciences on the subject of prepared milk. says that the composition of milk is not uniform; proportions of caseine, sugar of milk, and butter , as is well known, with the nature of the mother's . "I take," says M. Liebig, "for the base of my position the normal form of woman's milk, after the ysis of M. Haidlen, of Giessen, and of which 1,000 s contain 31 parts of caseine, 43 of sugar of milk, 31 of butter. The plastic and heat-giving sub-ces in this milk amount to 10 in 38; in that of the unskimmed, as 10 to 30; and in the same skimmed, 10 to 25. I employ for my preparation skimmed k, wheat flour, sprouted barley, and bi-carbonate of ash. It cannot be said that starch is unfit for the rishment of infants; but it is nevertheless true that transformation into sugar in the stomach imposes less labour on the organisation of the suckling; this spared by first converting the starch into sugar, or ble dextrine. This consideration accounts for my use germinated barley, or malt, in my preparation; it is o important that the consistency of the mixture ould be such that it can be administered by means of feeding-bottle." The preparation of the artificial k is thus described:—Sixteen grammes of flour are led in ten times its own weight of skimmed milk until e mixture is perfectly homogeneous; it is then re-oved from the fire, and immediately afterwards is led to it 16 grammes of the barley ground in a coffee ill, and mixed with twice its weight of cold water d three grammes of a solution of bi-carbonate of otash, consisting of 11 parts of water to two parts of he salt. After the addition of the barley and bi-car-onate, the vessel is placed either in hot water or in a arm position until the mixture shall have lost its thick-ness, and assumed the consistency of cream. At the end of

fifteen or twenty minutes the vessel is again placed on the fire and allowed to boil for a few seconds, after which the milk is passed through a close linen or hair strainer, in order to clear it of its fibrous matter of the barley. Before giving this milk to the child, it should, however, be allowed to stand at rest, so that the finer fibrous matter still held in suspension may subside. Milk prepared after this method contains almost exactly the same flesh-making and heat-giving substances as normal woman's milk, that is to say, 10 in 38, and after being carried to the boiling point it will keep good in summer for twenty-four hours.

GLYCERINE GLUE.—A German chemist, M. C. Puscher, has discovered that, if glue or gelatine be mixed with about one-fourth of its own weight of glycerine, it loses its brittleness, and becomes applicable for many purposes for which it is otherwise unfit. M. Puscher uses mixtures of this kind for dressing leather, preparing artificial bones, for giving elasticity to parch-ment and porcelain, or enamelled paper, and for book-binding. A cement composed of starch, glycerine, and sulphate of lime is said to remain plastic and adhesive, and is recommended for luting chemical and philosophical apparatus, and other similar purposes. Glycerine glue is said to possess many of the qualities of india rubber, and particularly that of erasing the marks of blacklead pencils. If wax be added to a mixture of gelatine and glycerine, and sicc yellow be used as a ground for the application of aniline red, the colour produced is said to be brilliant in the extreme.

Commerce.

INTERNATIONAL MARITIME EXHIBITION AT HAVRE.—A very interesting exhibition is announced to take place at Havre in the spring of next year. The word *maritime* is used in the very widest sense, as will be seen by the following extracts from the classification:—The exhibition will be divided into 43 classes, in five groups:—1. All that appertains to navigation, construction, rigging, fittings, and machinery.—2. Samples of all the com-modities which enter into the commerce of Havre, tex-tiles, colonial produce, indigenous commodities, cereals, fruits and seeds; dye stuffs, fatty substances, wood, metals, &c.; one class being reserved for the exhibi-tion of methods of packing, for which our neigh-bours, the French, have a remarkable superiority over ourselves.—3. Fishing tackle, apparatus, imple-ments, and accessories of all kinds, whether relating to deep-sea, river, or shore fisheries; and plant and utensils for the preparation of fish, either on the spot where they are taken, or elsewhere.—4. Agricultural implements and produce.—5. Art as applicable to the marine, such as models and sections of vessels, &c.; and art proper, such as pictures, studies, water-colour draw-ings, marine photographs, &c., manuscripts, books and pamphlets relating to the history of maritime science, and treating of the importance of international maritime commerce, with a view to general progress, humane societies, &c.; aquatic sports, founded either on historical events, or fabulous and legendary subjects. The plan also includes a salt-water aquarium, on a grand and new plan, in which may be exhibited all the interesting and rare species of fish found in the embouchure of the Seine, the Channel, the North Sea, and the ocean. Yachts and pleasure-boats of all kinds are also included in the programme. All applications for space are to be made before the 1st of January, either to the direction of the exhibition at Havre, or to the agents appointed to repre-sent it abroad. The managers have determined to charge the following fixed fees for space, to cover expenses, in-surance, and surveillance. In enclosed galleries, 25 fr. per square metre, 15 fr. the half-metre, and 10 fr. the quarter metre; on the inner wall, 10 fr. per metre; in

the open air, 5 fr. per metre, or with permission to erect sheds or roofs, 10 fr. No charge will be made for pictures or other works of pure art. Books, memoirs, &c., to pay 5 fr. each, but the direction will supply the necessary book-shelves, &c. Exhibitors may either provide their own counters or stands, or the management will undertake them at the following rates:—Counters or supports, capable of carrying objects weighing up to 4 cwt., 5 fr. per metre; 3 fr. for the half; and 2 fr. for the quarter metre. Exhibitors paying more than 100 fr. to the direction will have certain advantages in the way of publicity by means of advertisement within the building itself and in the columns of the *Gazette de l'Exposition*, and other exhibitors may obtain the same advantage by the payment of 25 fr. This plan of charging, at fixed rates, for space, and other matters, is new, and may be worthy of attention with regard to local or special exhibitions where the general attractions are unlikely to promise sufficient income to cover expenses.

THE HISTORY OF BEETROOT SUGAR.—The following remarks on the above subject, says the *Toronto Weekly Leader* of May 24th, are taken from a recent pamphlet which is now attracting a good deal of interest in Canada:—In 1810, M. Deyeux, a member of a committee previously appointed by Napoleon I. to investigate the subject of the manufacture of beet sugar, made his report, and presented two leaves of sugar equal in every respect to the best sugar from the cane, but neither the percentage of sugar obtained nor the cost of production was given. Reports not well verified were published, that in Germany from 4 to 6 per cent. of sugar had been obtained. By the experiments of M. Barruel, from 50 to 60 per cent. only of juice was obtained from the beet, whereas the production at the present time is from 80 to 85 per cent. The yield of sugar was about 1½ per cent., while at the present time in France it is about 7 per cent.; in Germany, 8 to 9 per cent.; and in Russia, 9 to 10 per cent. The cost was nearly 30 cents. per pound, while at the present time it is about 4 cents. M. Derosne, a Frenchman, obtained in 1811 about 2 per cent of sugar from the beet. Other experiments yielded 2½ per cent. A factory working 500 tons of beet in a season was considered quite extensive. There are establishments now in operation that work 60,000 tons. A rasp then worked about 3 tons per diem. Now from 150 to 300 tons a day are consumed by one rasp. In 1812 the cost of manufacturing sugar was about 9 cents. per pound. Chemical schools and imperial factories were established, and Government ordered the cultivation of 100,000 acres of beet. In December, 1814, favourable tariff duties infused new life into the industry; manufacturers introduced great improvements in their establishments, to such an extent that they obtained 70 per cent. of juice from the beet, in lieu of 50 and 60 per cent. The yield of sugar was from 3 to 4 per cent., and of molasses about 5 per cent. M. Crespel Delisse claimed that he obtained 5 per cent. sugar and 4 to 8 molasses. The cost of manufacturing was about 7 cents. per pound. From 1822 to 1830 the number of manufactories largely increased. The yield of sugar was about 5 per cent., and the cost of production about 6½ cents. per pound. In 1825 France produced 5,000 tons of sugar in over 100 establishments. From 1830 to 1836 great progress was made. The sugar produced was of improved quality, and amounted to about 5 per cent. of the weight of the beet worked. The introduction of steam power increased the means of production ten-fold. In 1836, 436 factories were in operation. Since 1840, the production of beet sugar in France has doubled every ten years. There were 60 manufactories of beet sugar in Austria in 1846; in 1865 the number had increased to 140. The states of the Zollverein have nearly quadrupled their production in the past 15 years, 52,586 tons having been produced in 1850, against 180,000 tons in 1865-6. The intimate relation between this branch of industry and agriculture developed itself, and there were no longer unimproved lands in the vicinity of a sugar manufactory. In the department of the North,

where the industry was most firmly established, the number of acres under cultivation in grain increased enormously, the beet pulp furnishing farmers with the means of feeding an increased number of cattle, thus providing the means of fertilising an increased amount of land. *L'Echo Agricole* says that "all farmers who obtain first prizes at the agricultural exhibitions are either sugar manufacturers, distillers, or cultivators of the beet. Those who have adopted this branch of agriculture, either as proprietors or tenants, have obtained really astonishing results. M. Vallerand, who took the first prize in the department of Aisne, bought, in 1853, a farm of 832 acres, the sales of produce of which amounted to 8,000 dollars. In 1859 it produced 41,500 dollars. M. Dargent, who took the first prize in the department of Seine Inferieure, cultivated only 60 acres. He so increased the production of this farm that he obtained 154,000 pounds, or 68 tons and 168 pounds, of beet from a single acre. The culture of the beet involved the necessity of deep ploughing, heavy manuring, and thorough weeding. The pulp from the juice extracted in the manufacture is an excellent food for cattle, the number of which has been increased in the districts devoted to that industry, from eight to ten-fold since the introduction of sugar making. The cattle furnish an immense amount of manure, which, applied to the deeply ploughed and well weeded beet lands, enhances their productiveness for the cereal crops."

Colonies.

THE GRAIN PRODUCED IN VICTORIA.—At a show of grain and other produce, under the auspices of the Board of Agriculture, the grain was the best ever seen in the colony. As large prizes were offered, the wheat had to be shown in lots of 40 bushels each, and the first prize sample weighed 68 lbs. 6 oz. per bushel, the second best weighing 68 lbs. 14 oz., but it was not so clear and pure, and the third lot the same as the first. The prize barley was shown in lots of 20 bushels each, weighed from 58 lbs. 2 oz. to 58 lbs. 6 oz., and the short oats from 46 lbs. to 50 lbs. 12 oz. to the bushel.

THE EXPORTS FROM QUEENSLAND last year show a moderate increase over the previous year, the totals being, 1865, £1,153,104; 1866, £1,366,491. There was a steady progress in everything but gold dust and tallow, in which there was a small decrease. The exports of timber are much increased, and copper ore has nearly doubled in the year, the exports being for 1865, £33,918. The shipment of cotton wool increased from £12,197 to £19,618. The exports of live stock are nearly six times larger than in 1865, amounting to £38,970 in 1866.

Obituary.

SIR THOMAS PHILLIPS, Q.C., was born in the year 1801, in the little mountain valley of Llanelly. His father was one of the managers of the neighbouring works and his mother, to whose influence he was accustomed to trace much of the energetic sense of duty which characterised him, was one of the Jameses of Llangotock, representatives of Sir David Gorn. He was articled to a solicitor, and at the expiration of his articles he became partner in the firm which, under the name of Prothero and Phillips, held the leading position in that part of the kingdom. It was while he was Mayor of Newport that the disaffection in the mining districts of South Wales culminated in the Chartist outbreak of 1839, to the imminence of which he had repeatedly, and in vain, called the attention of the Government. Having obtained the assistance of 30 soldiers, under a young subaltern,

he awaited the approach of the insurgents in the Westgate Hotel, and while opening the most exposed shutter of a bow window, to enable the troops to fire, he was seriously wounded in the arm and side. After the removal of the rioters he continued to attend to business, and his brother, the late Mr. B. Phillips, F.R.S., F.R.C.S., an eminent surgeon, saw considerable reason to dread ockjaw, but happily this did not supervene. Soon after his recovery he received the freedom of the City of London, the thanks of various public bodies, and a service of plate, and was knighted by the Queen at Windsor. He then proceeded on a tour in the East, taking with him the unfortunate artist Dadd, and on his return was called to the bar, and obtained considerable success in Parliamentary practice. He now threw himself into various public and charitable pursuits, and became an active member of the governing bodies of the National Society, King's College, the Church Institution, and other kindred societies in the metropolis. At the same period he founded a school near his colliery at County Bella, which became the model of those which have contributed largely to convert the disaffected natives of those districts into peaceful and loyal subjects. To him was mainly owing the success of Brecon College, in whose management, as well as that of many charities in the diocese of Llandaff, he took an active interest to the end of his life. He was an active member of the country magistracy, and for several years acted as Deputy-Chairman of Quarter Sessions for Monmouthshire. He became eventually a Queen's Counsel and a bencher of the Inner Temple. Sir Thomas Phillips received a service of plate for his services as Chairman of the Committee of Creditors when the failure of the New-Port banks threatened disaster to the whole neighbourhood. In July, 1860, he was elected Chairman of the Council of the Society of Arts, and served the office for three years, including the period of the International Exhibition of 1862, this being the first occasion of the Society's altering its rules with regard to the re-election of its chairman. He was again elected in July, 1866, and held the office at the time of his death. He was addressing a Committee of the House on Tuesday, May 1st, when he was struck with paralysis. He never lost consciousness, and was removed in Sir Thos. Watson's carriage to his nephew's house in Gloucester-place, where he expired on the following Sunday. His remains were removed to Llanellen, where he was buried near his father and mother. In him the poor have lost a kind and discriminating friend, and the Society a valuable and energetic supporter.

Notes.

ROYAL ACADEMY OF SCIENCES, BELGIUM. — The Academy has issued the four following subjects, for prizes of the value of one hundred francs, to be awarded in the year 1868:—1. Examination and discussion of the methods in use to ascertain the declination, inclination, and magnetic intensity of the earth, as well as the secular and diurnal variations.—2. Discussion and improvement with respect to any important point of the theory of the form of waves.—3. A complete study of a natural organic alkaloid, containing azote and oxygen, quinine in preference to any other; the object being to elucidate the constitution of this substance, and to determine the place which it should occupy in serial classification.—4. The anatomic composition of the egg in various classes of the animal kingdom, its mode of formation, and the functions of the various parts of which it is composed. The papers to be written in Latin, French, or Flemish, and sent in before the 1st August, 1868, with name of author, in a sealed letter, to Mr. Quetelet, perpetual secretary of the Academy. It is not stated whether the prizes are offered for general competition.

Correspondence.

OUR RIVERS AND WATER SUPPLY.—SIR,—The reported saying of a great but unlearned engineer, "that rivers were created for the supply of navigable canals," has been one of the causes of their very neglected state, for the principal object held in view in the management of our rivers has always been inland navigation and water-power, as matters of considerable importance to former generations, but now falling into disuse, and for which we of the present generation are called upon to expend large sums in order to remedy the almost irreparable injuries inflicted upon every river and its tributaries throughout the kingdom. The question of water-supply, now so much agitated, must be solved by reference to the great laws of nature, as established by infinite power and wisdom, and not by having recourse to entirely artificial arrangements, which, whatever their nature, will still further contribute to the destruction of our rivers; whereas the enactment of a simple law to prohibit, after a certain period, the existence of dams and weirs for any purpose whatever in any river or its tributaries, so that it may have a clear course from its head to the sea, will be quite sufficient for the purpose of procuring an ample supply of pure water to all the inhabitants of the land; provided, of course, that at the same time all gross town sewage and refuse of manufactories be also prohibited from defiling our river waters. The storage of winter floods and their restoration to the river during the dry months, are proceedings closely allied to the well-known system of warping, which, though it may render some lands fertile by the deposition of silt, is ruinous to the river, and is at times the cause of terrible destruction. For it is an undoubted axiom, that every drop of water lost to the river in time of flood causes a proportional rise in its bed, and consequent disastrous inundations at every extraordinary overflow. The principle of storage, so strongly recommended in the paper on the subject of "Water Supply," read at the meeting of the Society on Wednesday, the 6th instant, must therefore be condemned as not only expensive, dangerous, and inefficient, but also as certain to entail enormous future outlay in the management of our rivers, which can only be considered in one light, namely that of their being the natural drains of the country they traverse. In order to promote that object, they must be so directed as to scour out their beds as deep as possible in respect to the land. They must not be hampered with arbitrary obstructions, and must be kept in their true course by means of embankments where necessary, sufficiently high and permanent to prevent any loss of water during the time of any extraordinary flood, and excessive bends should also be obliterated by means of short cuts. If the isthmus forming the Isle of Dogs were cut through, so as to straighten the course of the river, the increased scour would in time very much lower all the sand-banks and shoals from that point to the Nore, besides affording, without cost, almost unlimited dock-room in the intercepted portion. Vested rights in dams, weirs, and locks are now nearly null and void, for the Canal Commission is in a state of bankruptcy, and was so previously to the advent of the railway system, for the inland navigation dues, like their relatives the turnpike tolls, never produced sufficient funds to meet interest, repairs, and restorations, seeing that all the locks and weirs are universally in a state of complete rottenness. In fact, application has been threatened for Parliamentary assistance, and we are to be taxed for the benefit of millers, manufacturers, and canal bargemen, over and above all costs, losses, and damages arising from the past, present, and increasing dilapidation of our rivers, both large and small. I cannot conclude without noticing the infatuation which prevails in regard to water-side premises, where you will see the pump applied to clear the basements from water after

every extraordinary tide, which happens at least twice in every year. Witness the new Palace at Westminster, and the Abbey, so built that at every high tide the basements are flooded, a situation which, in the case of the Parliamentary buildings, has added a million or two to their necessary cost.—I am, &c., HENRY W. RAVELRY.

1, Baker-street, Reading.

WATER SUPPLY.—**SIR.**—In the discussion on Mr. Bailey Denton's interesting paper, "On the Water Supply of the Metropolis," on the 6th inst., in the second part of my observations, what I meant to convey was the necessity of drainage as a preliminary to the successful culture of strong, wet lands; also that, useful as Italian rye-grass was found to be, it is a great exhauster, and where the land was not in very good heart, I had seen on three farms in different localities the succeeding crop almost a failure.—I am, &c., W. BOTLY.

Journal of the Society of Arts.

FRIDAY, JUNE 21, 1867.

Announcements by the Council.

VISIT TO THE PARIS EXHIBITION.

The Council have directed the Secretary to make arrangements for a visit of the members of the Society to the Paris Exhibition. The period for this visit is not yet fixed, but it will probably be towards the latter end of July.

ARTIZANS' VISITS TO PARIS.

The Council of the Society of Arts, feeling the importance of promoting the intelligent study of the Paris Exhibition and the manufacturing establishments in France by artisans of the United Kingdom, have appointed a Committee in furtherance of this object, and on their recommendation, have passed the following minute:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government, to facilitate the visits of skilled artisans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund to be employed, in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of the grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join in a subscription for the furtherance of the undertaking;

and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

Members are invited to aid the Council in this undertaking by subscriptions, which should be forwarded to the Financial Officer at the Society's house.

The following is the list of subscriptions up to the present date:—

H.R.H. the Prince of Wales, President	£31	10	0
Society of Arts	105	0	0

A circular has been issued by the Birmingham Chamber of Commerce, "earnestly asking for the co-operation of manufacturers and others, believing it to be of the highest importance that the opportunity now afforded, by which the workmen of our town may be made acquainted with the productions of continental manufacturers, should not be lost," and inviting subscriptions.

SUBSCRIPTIONS.

The Lady-day subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

FINANCIAL STATEMENT.

The foregoing statement is published in this *Journal*, in accordance with Sec. 42 of the City's Bye-laws, which provides that, at the annual General Meeting, the Council shall render the Society a full account of their proceedings, of the receipts, payments, and expenditure during the past year; and a copy of such statement shall be published in the *Journal* of the Society on the Friday before such general ting.

ANNUAL GENERAL MEETING.

The One Hundred and Thirteenth Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' statement of receipts, payments, and expenditure during the past year, and also for the election of officers, will be held, in accordance with the bye-laws, on Wednesday next, the 26th of June, at four o'clock p.m.

The Council hereby convene a Special General Meeting of the members of the Society for ballot for members, such meeting to take place at the close of the Annual General Meeting.

By order,

P. LE NEVE FOSTER, *Secretary*.

Society's House, Adelphi, June 19th, 1867.

Proceedings of the Society.

SIXTEENTH ANNUAL CONFERENCE.

The Sixteenth annual Conference of the Representatives of the Institutions in Union, and the Local Educational Boards, with the Council of the Society, was held at the Society's House on Wednesday, the 19th inst., at 12 o'clock noon. The Right Hon. Henry Austin Bruce, M.P., presided.

The following is a list of the Institutions and Local Educational Boards represented at the Conference, with the names of their respective representatives:—

Banbury Mechanics' Institute	{ Mr. R. Heygate
„ Local Board	{ Mr. J. H. Beale
Birmingham and Midland Institute	{ Mr. W. C. Aitken.
Bromsgrove Literary and Mechanics' Institute	{ Mr. H. F. Vernon, M.P.
Carlisle Mechanics' Institute ..	{ Mr. T. H. Gretton.
Chelmsford Literary and Mechanics' Institute	{ Mr. E. Potter, M.P.
Colchester Literary Institute ..	{ Mr. John Gibbs.
Dudley Mechanics' Institute ..	{ Mr. Thomas Moss.
Glasgow Institution	{ Mr. C. H. Hawkins.
„ Mechanics' Institution ..	{ Mr. C. Twamley.
Hertford Local Board	{ Mr. E. Holbrey.
Huddersfield Mechanics' Institute	{ Mr. Alexander Craig.
	{ Mr. William Graham, M.P.
	{ Mr. R. Dimsdale, M.P.
	{ Mr. John Sugden.

Hull Young People's Institution	Mr. Paul Blackmore.
Lancashire and Cheshire Union of Institutes	Mr. Alderman Rumney, F.C.S.
Lancaster Mechanics' Institute	Dr. R. M. Pankhurst.
London, Birkbeck Literary and Scientific Institution	Dr. John Watts.
„ City of London College	Mr. Thomas Lawton.
„ Lambeth Local Board ..	Mr. J. S. Harrison, J.P.
„ Metropolitan Association	Mr. E. Storey.
„ Walworth Literary and Scientific Institution ..	Mr. G. C. Sherrard.
Macclesfield Useful Knowledge Society	Mr. J. Rigby Smith.
New Swindon Mechanics' Institute	Rev. J. Maskell
Ryde (Isle of Wight) Philosophical and Scientific Society	Mr. J. Knight
South Staffordshire Association	Mr. J. H. Levy
West Riding Educational Board	Mr. F. Reynolds.
Woolwich Royal Laboratory Local Board	Mr. T. E. Heller.
Worcestershire Union of Institutes	Rev. John Oakley.
Yorkshire Union of Institutes	Mr. Thos. Whittington.
	Mr. R. Strong.
	Mr. F. Wood.
	Mr. W. Bullock.
	Mr. W. L. Fallows.
	Rev. J. S. Barrow.
	Mr. Thomas Webster, Q.C., F.R.S.
	Lord Lyttelton.
	Mr. J. N. Langley.
	Mr. F. Talbot.
	Mr. H. H. Sales.
	Mr. J. Anderson.
	Mr. George White.
	Mr. F. Marcus.
	Mr. James Hole.

The Conference was also attended by the following, amongst others:—

Mr. Harry Chester, Vice-President of the Society.
 Mr. Benjamin Shaw, Member of Council.
 Mr. G. F. Wilson, F.R.S., Member of Council.
 Mr. E. C. Tufnell, Examiner in Domestic Economy.
 Mr. John Sykes, Examiner in Mensuration.
 Mr. F. S. Cary, Examiner in Freehand Drawing.
 Professor Hughes, Examiner in Geography.
 Mr. I. F. Iselin, Government Inspector of Science Schools.
 Mr. B. Waterhouse Hawkins.

The Secretary read the following

REPORT TO THE COUNCIL OF THE SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.

GENTLEMEN,—In presenting this year my report of the Proceedings of the Union of Institutions, I have the satisfaction of recording a very considerable increase in the number of those who have presented themselves at the Society's Final Examinations,—an increase especially noteworthy, inasmuch as last year I had to report a slight diminution as compared with the previous year, the first time since the establishment of the examinations that there had been any interruption in the regular annual increase that had been going on. The numbers examined this year have reached 1,439, whilst last year they only amounted to 1,096. In the previous year the number of those presenting themselves for examination was 1,199, still

largely below the numbers of the present year. The number of those who have successfully passed the examination has been 1,120 in the present year, as compared with 839 last year, a somewhat larger proportion, inasmuch as the percentage of those not passed is this year only 21·3, whilst last year it was 23·5. Neither of these years, however, compares favourably in this respect with the year previous, 1865, when the percentage of not passed candidates was only 16·6. These fluctuations, whether as regards the number of those examined, or the proportion of those who are successful, cannot be readily accounted for, though no doubt the increase in the numbers examined is due in a considerable degree to the continued working of the Visiting Officers in their several districts. It is certainly very desirable that the number of these District Unions should be increased, and it will be seen that the question, "Whether any additional means can be devised to induce the Institutions to form District Unions, with paid Visiting Officers, in connexion with the Society of Arts?" is to come on for discussion at the Conference.

The reports of these officers, showing what has been done in their respective districts, are given at length in the Appendix.

Notwithstanding that this year the percentage of unsuccessful candidates has somewhat diminished as compared with last year, it still remains larger than it ought to be, especially when we bear in mind that only three years ago the percentage was considerably less, as the figures given above show. This is a matter which the Local Boards should seriously take into consideration, as with them rests the responsibility of admitting the candidates to the examinations. If the Boards are lax in this respect, unnecessary disappointment falls upon the candidates and discouragement ensues. I am well aware that I am repeating what I have said on this subject on former occasions, but I feel so strongly the importance of a strict attention on the part of the Local Boards to this portion of their duty that I think I am not over-stepping my province in calling the attention of the Boards to this matter so long as the proportion of unsuccessful candidates still remains so large. On the other side, it is but fair to the candidates generally, and to the character of the examinations as a whole, that I should state that in the opinion of the examiners the work is well done, and in many of the subjects they speak in the highest terms of the qualifications of the candidates.

The remarks of the examiners will be found in the appendix annexed to this report.

The following tabular statement shows the comparison of the present year's examinations, in its various details, with that of the two previous years:—

	1867.	1866.	1865.
No. of Local Boards at which Final Examinations were held	120	99	100
" Candidates examined	1,439	1,097	1,199
" " passed	1,120	839	999
" " unsuccessful	319	257	200
" Papers worked	2,050	1,571	1,744
" 1st class certificates	339	203	316
" 2nd class certificates	516	421	519
" 3rd class certificates	664	520	517
" unsuccessful papers	532	427	393
" Prizes awarded	61	51	51
Prizes in amount	£266 5s.	£230 5s.	£211 5s.

I have taken the two previous years' returns rather than the last year only, because, as I have said before, a comparison with that year only would not have fairly represented the progress which these examinations are making.

The Prince Consort's prize is this year taken by William Meadows, aged 19, of the City of London College, clerk, who in this and the three preceding years has obtained the following first-class certificates:—

- 1864. Chemistry—First-class Certificate, with First Prize.
- " Animal Physiology—First-class Certificate, with First Prize.
- " Geometry—First-class Certificate, with First Prize.
- 1865. Book-keeping—First-class Certificate.
- 1866. Navigation and Nautical Astronomy—First-class Certificate, with First Prize.
- " Principles of Mechanics—First-class Certificate, with First Prize.
- " Algebra—First-class Certificate.
- 1867. Arithmetic—First-class Certificate, with Second Prize.
- " Domestic Economy—First-class Certificate, with First Prize.
- " English Literature—First-class Certificate, with First Prize.
- " Mensuration—First-class Certificate, with First Prize.

The special prizes offered by the Royal Horticultural Society for gardeners, by the proprietors of the *Gardeners' Chronicle*, by the Royal Geographical Society, by the Worshipful Company of Coach and Coach Harness Makers, and by the Worshipful Company of Goldsmiths, have, with two exceptions, been taken. The particulars have already been published in the *Journal*.

In compliance with the wish expressed at the last Conference, the Society of Arts offered special prizes to females in sixteen subjects, and though I regret to say that only two of these prizes were taken, the offer appears to have been productive of good effect, inasmuch as there has been a considerable increase in the number of Female Candidates; 64 having offered themselves for examination, and 57 having obtained certificates.

In the Elementary Examinations held by each of the District Unions and Local Educational

As we have availed themselves of the elementary papers issued by the Society, the certificates being awarded by the local authorities themselves, there has been likewise a very considerable increase in the number of candidates of both grades. Although, as I mentioned in my report last year, the fact of these elementary papers as well as the forms of certificates supplied by the Society of Arts led, in some instances, to the erroneous impression that examinations were held and the certificates issued by the Society's own examiners,—an

error which, if it ever became very prevalent, must lead to the total discontinuance of the aid thus afforded by the Society to elementary education,—the Council decided to continue it this year, and the results have, I think, fully justified this course, the increase in the number of candidates being so considerable that it would be a matter of regret that any circumstances should render it necessary to withdraw the assistance thus given to local effort. The results of this year's Elementary Examinations are given in the following table:—

ELEMENTARY EXAMINATIONS, 1867.

Name of Union or Local Board.	Number of Centres.	HIGHER GRADE.				LOWER GRADE.			
		MALE CANDIDATES.		FEMALE CANDIDATES.		MALE CANDIDATES.		FEMALE CANDIDATES.	
		Examined.	Passed.	Examined.	Passed.	Examined.	Passed.	Examined.	Passed.

It appears, then, that in 1866, these examinations were held by 21 District Unions or Boards at 112 centres; this year, 19 District Unions or Boards have held them at 113 centres. In 1866, there were 1,814 candidates, of whom 1,006 obtained certificates. Of these, 442 were candidates in the higher grade, of whom 260 obtained certificates; 1,372 in the lower grade, of whom 746 obtained certificates; this year the whole number of candidates examined was 2,864, of whom, however, only 1,393 obtained certificates, the proportions being 646 higher grade, with 392 successful; and 2,208 lower grade, with 1,001 successful, a smaller percentage than last year. Among the higher grade candidates were 45 females, obtaining 31 certificates; and among the lower grade were 413 females, with 230 successful; while, last year, there were in the higher grade 18 females, 9 of whom were successful; in the lower grade, 273 females, with 128 successful.

These numbers include the candidates examined

by the Metropolitan Association for Promoting the Education of Adults—a body formed only a few years ago, but which is, I think, steadily increasing in usefulness and advancing in public estimation. This Association preferred, as on former occasions, to use elementary papers prepared by their own examiners, but essentially similar to those issued by the Society. In their elementary examinations the above table shows that there has been a very considerable advance upon last year. In 1866, the candidates examined by this Association were as follows:—In the higher grade 37 male and 20 female candidates, of whom 13 and 14 respectively obtained certificates; in the lower grade 231 male and 57 female candidates, the certificates awarded being 150 to the former and 32 to the latter. The numbers this year, as given in the table, show a very considerable increase; they are—Higher grade, 72 male and 18 female candidates, of whom 52 and 11 respectively received certificates; in the lower grade, 255

encourage the adult operatives to give attention to the important matters Writing and Composition, the Council of the Union have instituted a system of special prizes, for essays, &c., on subjects in which the working classes are supposed to be interested. Essays have this year been written on the "Wages Question," "Cooperation," "Improvements in Machinery, &c." Special prizes are offered to the two candidates who this year shall obtain the highest aggregate number of marks at the Society's Examination. The Council propose for next year to distribute the subjects in the programmes of the Society and of the Science Department into ten groups, and award money prizes to candidates obtaining the greatest number of marks in each group. The Chairman of the Council (Mr. Alderman Rumney) has kindly consented to award a scholarship of £50 per annum, tenable for three years, in Owen's College, Manchester, to the artisan who, in 1869 and the two years immediately preceding it, shall obtain the highest aggregate number of marks at the examination held under the auspices of the Union. It is gratifying to report a considerable increase in the number and efficiency of Evening Classes for Females; and this increase is, to some extent, attributable to the special prizes offered to female candidates for "cutting-out and needlework." No candidate is allowed to compete for the prizes unless she has passed the Elementary Examination. During the past winter I have inspected the Evening Classes of 61 Institutes, delivered 30 addresses at public meetings, and attended 20 meetings of committees.

Mr. W. G. Larkins, of the Metropolitan Association for Promoting the Education of Adults, writes:—

The candidates examined in the Elementary Examinations this year have come from 35 Institutions. While the return shows an increase in the number of candidates, it also shows a decrease in the number of certificates granted. This is owing to the fact that a great many candidates did not take up the extra subject required in which they must pass in order to obtain a certificate. So far as they were examined, they showed considerable merit. Some, again, while they passed in perhaps two extra subjects, did not take up arithmetic, which is also compulsory. The examiners report that the papers sent in are on the whole satisfactory, especially in the higher grade. From a personal canvass of most of the Institutions, Night Schools, Working Men's Clubs, &c., I can but be of the opinion that the Elementary Examinations are appreciated, and their advantages acknowledged. There is, however, a feeling that the step between the Elementary Examinations and the Final Examinations is too great. There are many who can satisfactorily pass the higher grade examinations of the Metropolitan Association, but who are not sufficiently advanced to proceed to the further examination of the Society of Arts. This might possibly be remedied either by the establishment of a lower grade by the Society of Arts, or by the Metropolitan Association forming a yet higher grade than it now has. Another reason why there are so few candidates who come up to the Final Examination from the Elementary may be found in the fact that few of the Institutions afford facilities for the instruction of candidates in the many subjects in which the Final Examinations are held. The Elementary Examination requires a tolerable knowledge of arithmetic, with English history or geography, and a candidate obtaining a certificate has enough knowledge of each for all practical purposes. He feels that he will obtain no benefit by a further examination in them; his studies have not embraced any other subjects in which to be examined. This, of course, applies more particularly to night-schools, working men's, and, in general, evening classes. In some of the higher-class Institutions, of course, greater facilities for instruction exist, and members can qualify themselves for the examinations.

Taking office only at the close of last year, I have had barely time to make myself acquainted with the details of the work of the Society of Arts. I may therefore be pardoned if I am unable to offer much in the way of suggestion or extension; I may, however, say that I have been greatly struck with the response that has been made to my endeavours thus far, especially where I have broken new ground.

Mr. F. Marcus, of the Worcestershire Union of Educational Institutes, writes:—

The work of the Union has made steady progress during the past year. There has been an increase in the number of institutes and night-schools in union; the number of artisan members and scholars in evening classes is also greater than last year. The candidates for Elementary and Special Examinations and for those connected with the Society of Arts, have increased from 591 to 904. Considerable additions have been made to the list of subjects for the Union special examinations, the prizes offered for needlework and domestic economy being amongst the most successful. The increase in the number of candidates for the Society of Arts' Final examinations is the most gratifying feature, as the certificates obtained are satisfactory assurances of real intellectual work and acquirements, and are, as such, valued by the recipients. The great drawbacks are, the very low state of the funds of the Union, and the little real inclination manifested by the managers of many institutions to make them subservient to the educational wants of the adult artisan population of the special locality.

Mr. H. H. Sales, of the Yorkshire Union of Institutions, writes:—

Increasing activity in the educational classes of Mechanics' Institutions, and greater earnestness and zeal on the part of the managers, mark our work in this Union at the present time. Systematic instruction, stimulated and encouraged by our various examinations and prize schemes, is becoming general throughout the Union, and good results are already seen, in a larger and more regular attendance of members. The Examinations of the Society of Arts are in every way adapted to the class-work of Institutions, and are welcomed by all engaged in adult education. Years must, however, pass away before the number of candidates will be largely increased, not from any defect in the scheme, but in consequence of the lamentably low standard of the great majority of the manual labour population. It matters little what may be the statistical returns respecting the state of education, for one fact cannot be disputed. The small success of our Institutions, compared with what might be gained, is mainly due to the defective education of the class members, who, having had but scanty, soon-forgotten instruction in the primary school, have, under all the difficulties attendant upon study after the work-day is past, to commence in the Institute the alphabet of knowledge. Practical men will not quibble concerning the exact number of thousands of uneducated children and youths in our midst, but will acknowledge the existence of a huge mass of ignorance in every seat of industry, which must be removed before larger results can be gained in our Institutions. The attention of the Union has long been prominently directed to the Paris Exhibition in relation to industrial instruction in Mechanics' Institutions. Whether English manufactures—the produce of English skill—are or are not superior to foreign workmanship, is within the region of controversy, but that instruction in industrial science is of paramount importance to a manufacturing community is beyond question. This instruction, founded on a liberal national basis, has yet to be commenced. The operations of the Department of Science and Art have hindered rather than promoted this instruction. Tentative in their existence, ever variable in their regulations, frivolous and vexatious in the

manipulation of details, it is no matter of surprise that managers care not for an alliance. The returns of the last examination for the whole country, tabulated and issued by the West Riding Educational Board, will show, judging by those already issued, how impossible it is to maintain that the present science aid can in any, but the very smallest degree, affect the great and momentous question of industrial education. To the Society of Arts, established to promote manufactures equally with arts and science, standing aside from all political parties, departmental influence, and commercial rivalry, the managers of the Institutions in this Union look to take action in directing national attention to the consideration of industrial instruction as an important component of national education.

Mr. F. Talbot, of the South Staffordshire Association for the Promotion of Adult Education and Evening Schools, writes:—

"There are in Union with our Association 21 Institutions, 6 Working Men's Clubs, and 31 Evening Schools, and they are all, with one exception, connected with the populous iron and coal-producing district of South Staffordshire. With regard to our Evening Schools, our Union will do all in its power to make them efficient, both for the purpose of their primary object, the improvement of elementary education, and to make them useful for the promotion of secondary education. Already several of them are sending in candidates for the Society of Arts' examinations, and the number will go on increasing year by year. Next to the Evening Schools we have some promising Young Men's Associations. Hitherto these Associations have been merely meetings of young men for religious exercises, debates, &c., but our Union has been trying for some time to induce their promoters to give them a more distinct educational character, and to provide for their members some means of systematic study, by classes, books, and lectures. I have attended the meetings of about a dozen of these small Associations, and two of the most important of them, one in Bilston and one in Dudley, have applied for admission into the Union. Others will follow, and in three or four parishes some steps have been taken to organize Associations with Classes, for the especial purpose of preparing candidates for the Society of Arts' examinations. In the month of March an important meeting of representatives of Institutions was held in the Town-hall, Wolverhampton, under the presidency of Sir John Morris, the Mayor, when a very able address was given by Mr. R. Kettle, one of the County Court Judges of the district, explanatory of the objects and details of the examination scheme of the Society of Arts, and a series of resolutions, based upon the address, were unanimously and heartily carried. The objects of the meeting, and Mr. Kettle's address, were fully reported in the local papers, and did much good amongst the Young Men's Associations above referred to. Our Union will, I hope, arrange for two or three meetings similar to the above during the next winter. In the almost complete, but we may hope temporary, cessation of class teaching in Mechanics' Institutions, our present hope of progress in the matter of secondary education lies much in the movement which we may be able to communicate to these small Associations. I am glad to be able to report that the Handsworth Working Men's Club has sent in this year some candidates to the Society's examinations. This is the first instance of members of a Working Men's Club coming up for examination, and proves that whilst recreation is perhaps the chief aim of their promoters, intellectual advancement may be kept successfully in view at the same time. In September the Union will hold a special examination of candidates in Scripture, Political and Domestic Economy, Animal Physiology, and the Laws of Health. No candidate will be admitted who has not

taken the first-grade certificate of the Union at a previous examination. The prizes range from £2 to £5, and are offered by the Association, and by several men and others, friends of the Association. Our Union will hold a meeting for Athletic Sports in Burnley Park, in July. The object is to encourage boys to get a steady attendance at Evening Schools during the winter months, and no one will be allowed to come for the prizes that will be offered, unless upon the production of a certificate stating that he has attended school a certain number of times, and that his conduct has been good. For the first time in the history of the Association, the Committee have arranged to hold in autumn, an Industrial Exhibition of work done by scholars (both male and female), who have attended their respective schools with regularity during the past winter. The Committee are looking forward with much interest to this effort to promote industrial education, especially in regard to its inventive and artistic developments; and for the especial encouragement of the productions that may be contributed by men and young women, a committee of ladies is in course of formation. To promote the writing of essays by members of Institutions and Working Men's Clubs, the Committee have this year proposed three subjects for prizes. One subject is theological, one is social and political, and the third is industrial, and is thus stated in the programme: 'On the Proofs afforded by the International Exhibition at Paris of the Scientific and Artistic Education of the Workmen of Foreign Countries.' Of course the value of this latter essay must be persons who will have seen the Exhibition. After a period of much personal embarrassment, our Union is now free from debt, and the Committee are hopeful of being able to extend its usefulness, and to prove its adaptation to promote the interests of all those Institutions whose object is the improvement of adult education."

EXAMINERS' REMARKS.

The Examiner in *Arithmetic* reports a marked improvement in the Arithmetical papers for this year. The work, as a whole, has been carefully done, and the details have been very fairly worked out.

The Examiners in *Book-keeping* says:—"There is a larger proportion of papers obtaining first-class certificates than in 1866, while the proportion of third-class certificates and papers not passed is also larger. The following percentages indicate the relative proportions of the several classes for the year 1867:—1st class certificates 20 per cent.; 2nd class certificates 36 per cent.; 3rd class certificates 38 per cent.; not passed 6 per cent."

The Examiner in *Algebra* says:—"Looking at the work produced this year, I am able to say that it is usually good, and betokens a sterling advance in the ability and knowledge of the candidates. A large proportion have done the papers creditably, and a certain number have answered in a style and with a precision of thought and language which would do credit to a university class. The proportion of failures is rather below the average of last year." The Examiner then refers to the circumstance of some of the candidates in this subject having copied. This has been already alluded to in the *Journal*.

The Examiner in *Geometry* says:—"The papers generally are worked well, with a careful attention to the logical sequence; and the problems, being easy—and some not more than questions which would be likely to have been considered by students—have obtained a great many more answers than usual. I think there is decided progress."

The Examiner in *Mensuration* says:—"It will be observed that nearly three-fourths of the candidates have fallen below the second class; but I would remark that these have done the simple questions very fairly: two only, who obtained but 8 per cent. of the full marks, did

be said to have failed completely. Questions of the nature of a problem find in general but little favour, and are seldom attempted with success. There are, as usual, several cases in which the working ought to have had more explanation."

The Examiner in *Trigonometry* says:—"The quality of the answers in Trigonometry is improved. Some of the candidates write very creditable papers, though the number of candidates for examination is still very small."

The Examiner in *Conic Sections* says:—"There is a very marked and decided improvement in the quality of the answers given to the questions in Conics, both geometrical and analytical, in this examination. Not only are one or two papers remarkably good, and very creditable to the candidates, but the average level of the papers is much above that of late years. The marks which it has been my duty to return, support the opinion which I am glad to express so strongly; and I assure the Council that the result of the present year justifies the continuance by them of the subject of conics within the range of examination by the Society."

The Examiner in *Principles of Mechanics* says:—"I am very glad indeed to be able to put so many into the first class. The papers, as a whole, are very creditable to the students who have worked them, and appear to give evidence that mathematical principles, as applied to mechanics, are better taught and more fully understood in our schools and institutions. Those who have failed to obtain the requisite marks have come to the examination, in most cases, quite unprepared, and will need a year's close study before they should present themselves again. The papers of the first-class are extremely satisfactory."

The Examiner in *Practical Mechanics* says:—"The number of candidates for certificates in this subject has been very much larger than upon any previous occasion. The papers have been extremely well done upon the whole, two certificates of the first class, and thirteen of the second class, having been awarded."

The Examiner in *Light and Heat* has this year to remark again the want of proper preparation with a great number of the candidates. It is only by continual exercise in writing out the answers to the questions which may be proposed, that any student can make the best use of his knowledge in the limited time allowed for examination, so as to give correct, complete, and yet condensed answers to all the questions which are set before him.

The Examiner in *Chemistry* says:—"Many of the papers leave a good deal to be desired in the way of accuracy. Teachers of chemistry are apt to include in their courses of instruction a wider range of facts than their pupils can thoroughly master. Each step in the study of the science ought to be firm and clear, and even the very first steps ought to be samples of accuracy and clearness."

The Examiner in *Animal Physiology* says:—"Some of the papers were exceedingly good; the writers had evidently studied and got to understand their subject. Many showed a very fair knowledge; but a large number of the candidates were more anxious to show that they had learned by heart a series of technical terms than to make it clear to the examiner that they really understood what they were writing about. There was too much book-work—too little reflection over what had been read. There were also many instances of bad spelling, not only of technical, but also of common words."

The Examiner in *Botany* says:—"Although I consider but one candidate deserving of a first-class certificate and two of a second, yet on the whole the returns are satisfactory. The answers, even amongst those not entitled to a certificate, are often intelligent, and promise very fairly in future examinations."

The Examiner in *Floriculture* says:—"On the whole the papers of the present year show an advance on those of 1866. There is, however, room for further im-

provement, and I can but repeat the recommendation made last year, namely, that candidates should, as a part of their studies, practice the writing out of short pithy remarks on each of the subjects set down in the programme, comparing their own remarks with the statements in the text books, and repeating this from time to time, cutting out all superfluous words, so that they may get the essential particulars well impressed on the memory, and at the same time acquire a clear and condensed style of writing."

The Examiner in *Fruit and Vegetable Culture* says:—"In the examination papers of this year I observe a marked improvement on those of last. There is in them none of that pretentious science that characterised some of those; but where scientific subjects are dealt with it is apparent that the writer has made them a subject of study, and has proved them in his practice. There is also less of mere book knowledge than I observed in last year's papers. Taking them altogether, they are very creditable, while those of the first class are highly meritorious."

The Examiner in *Domestic Economy* says:—"Most of the answers display a very creditable knowledge of the subject, but many of the candidates seem to know far more than they are able to put into good English, and show an extraordinary deficiency in the power of composition. Bad grammar, and the absence of stops, often make it difficult to comprehend the meaning intended to be conveyed. Altogether, however, the answers are satisfactory."

The Examiner in *Geography* says:—"There is little that calls for remark in reference to the Geography papers for the present year. Regarding them as a whole, they render obvious a large amount of preliminary work—much of it work that has evidently been well and thoughtfully done. It is true that the papers to which only third-class certificates can be awarded bear a large proportion to the whole, but, considering the limited opportunities for study which may probably be assumed to have been at the disposal of many of the writers, there is no reason either for surprise or dissatisfaction at such a result. In the case of many among these (and in some of those that come under the head of 'not passed') there are evidences of the ability to do more with longer and better preparation. It cannot be too strongly impressed on intending candidates, that methodised study (as distinguished from merely desultory snatches at knowledge) is a condition indispensable to a high order of success. The first-class papers of the present year do very great credit to their writers."

The Examiner in *English History* says:—"I think that upon the whole the answers that I have received to the questions are more satisfactory than those of last year, and show a decided improvement, not only in the general knowledge of the candidates, but in the care with which they have studied the special subjects of the examination."

The Examiner in *English Literature* says:—"A large proportion of the papers are very satisfactory. On the whole they are certainly better than the papers of last year. The one to which I have given the highest number of marks has remarkable merit, and perhaps deserves to stand at a greater distance above the one that comes next to it than the mere number of marks would indicate. I regret to observe that, in spite of the repeated admonitions that have been given, there are some candidates who waste their time by copying out the questions on their papers."

The Examiner in *Logic and Mental Sciences* says:—"The number of candidates in this department is not equal to the two preceding years, but the quality of the work is very decidedly better. In Logic and Mental Philosophy the answers are generally good. The paper on Moral Philosophy has not been attempted."

The Examiner in *Latin and Roman History* says:—"The work of the best candidate is as good as I have ever had; the work of the worst is much above the worst

that I have ever had. The average is much as usual, except that the parsing is better."

The Examiner in *French* says:—"I am on the whole extremely satisfied with the papers this year, and am able to recommend no less than 91 candidates for certificates, a number much larger, not only absolutely speaking, but also in proportion to the total amount of papers received, than in any former year. This satisfactory result is, I think, mainly due to an improvement in the mode of working the papers. Too often, as I had occasion to remark in a former report, it seemed as if the candidates had imagined that their best chance of securing at least a second or third-class certificate was to aim anyhow at a first-class one; the almost invariable consequence in such cases being an utter failure. Now, I am glad to see that this year the scope of each paper is generally better defined and its aim less ambitious. The candidates have done all the better for Horace's precept:—

Sumite materiam vestris, qui scribitis, æquam
Viribus, et versate diu quid ferre recusat,
Quid valeant humeri.

The Examiner in *German* says:—"I do not remember ever to have had before me such good German compositions as those written by the best candidates this year."

The Examiner in *Italian* regrets that only two candidates should have taken up this subject. He has only been able to award a second and third-class certificate.

The Examiner in *Spanish* says that he thinks on the whole there is a general improvement.

The Examiner in *Free-Hand Drawing* says:—"There were eighty-six candidates whose drawings were submitted to me at this examination, which is a greater number than has been sent up in any previous year. I have awarded six first-class certificates, twenty-two second-class, thirty-one third-class, and twenty-six have not passed. The drawings are quite up to the general average, but the candidates have sadly failed in answering the four questions relating to the proportions of the human figure, only one out of the eighty-six having answered them correctly."

The Examiner in *Geometrical Drawing* remarks that "About 31 per cent. of the candidates only have gained a first or second class, and no less than 40 per cent. have failed to pass. This is the result of the same causes which have been mentioned in previous reports—First, a want of elementary knowledge of practical co-ordinate geometry; and secondly, attempted constructions which the candidates should have felt were beyond their powers. It should be stated that there were thirty questions for the candidate to select from, without any restriction, and it was assumed that in the allotted time he could not construct more than ten, while the credits were assigned so that seven would have given him a first class. The drawing generally is very fair, and in many cases very good."

The report of the discussion will appear in next week's *Journal*.

PARIS EXHIBITION.

Continuing the subject mooted in the last number of the *Journal*, we may safely point to the collection of decorated glass on the British side of the Exhibition as furnishing another instance of decided progress. In ordinary table glass, and perhaps also in flint glass decorated in a simple manner, the English manufacturers cannot compete with those of France; the forms of the latter are extremely elegant, and the prices very moderate; it is in the most costly articles, and those in which the largest amount of art enters, that the British show is conspicuous. Some of the specimens exhibited are really elaborate works of art; and as examples of what may be done in the ornamentation of glass, some of these *travaux de force* are certainly unsuited, and are destined to find their place in more than one public museum and private collection. The general progress shown in British decorated glass is certainly in keeping with that exhibited in the highly artistic objects referred to above; the forms as well as the "metal" are purer and more elegant than formerly, and the decorations are in better taste; the very general use of simple engraved leaves, flowers, ferns, and geometric forms, in place of the old-fashioned cutting, shows an improved taste and notion of fitness that should not be overlooked; they have called forth expressions of the highest admiration from our friendly rivals, who do not disguise their

surprise at the progress that has taken place in Great Britain in this manufacture since 1851. The great amount of skill exhibited in another branch of the glass trade has attracted almost as much attention, viz., the manufacture of what is called Venetian glass, in which the whole of the ornamentation is produced by the glass-maker himself, who turns it out from his hands completely finished. When it is remembered that the whole of the twists and waves which are the characteristics of Venetian glass are produced without the use of any mould, which would destroy the surface, and consequently, the pellucid character of the glass, and with no other aids than a few simple tools, and when we see the perfection of form and beautiful effects attained, the Venetian glass must be ranked very high as a product of pure industrial skill. There are specimens in the Exhibition which are not only full of grace in the design, but of which the forms are almost as perfect as if they had been turned on the wheel or moulded; and there are specimens which, for elaboration in the manufacture, can scarcely be surpassed.

In chandeliers and lustres the English manufacturers have formidable rivals, especially among the French makers, but, generally speaking, the forms are far lighter and more graceful than they were formerly; while the material, the cutting, and the modes of connecting the various parts are certainly also improved. The application of the Venetian glass to chandeliers and lustres, in imitation of an old style, also deserves notice, especially as regards construction and the skill of the glass worker.

The popularity of the Exhibition grows in the most remarkable manner; the number of visitors in a single day has probably already exceeded the expectations of the most sanguine; on Whit Monday, according to semi-official accounts, more than 120,000 persons paid for admission, and it is estimated that the total entries throughout the day must have amounted to 136,000. That a sum equal to £4,800 should be taken at the gates in one day, at this early part of the season, before the great mass of provincials and foreigners can leave home, is certainly an extraordinary fact; and it is highly satisfactory to note that not a single accident of any kind is recorded, and no special complaint heard of inconvenient crowding; this result must be attributed, in a great measure, to the large number of entrances, and, as we remarked last week, to the excellent means of ingress to the building itself.

The coming announcement of the awards is now looked forward to with great interest, and it is said that the list will be published in the last week of the present month.

On the 1st of July, at any rate, the awards will certainly be known, and the preparations for the grand ceremony of distribution are well advanced. It is announced that besides the Emperor and Empress of the French, there will be present on the occasion the Emperor and Empress of Austria, the Sultan and the Viceroy, now King of Egypt, the King and Queen of Portugal, the King of Sweden and Norway, the Prince of Wales, the Crown Prince and Princess of Prussia, and the representatives of the municipalities of London, Edinburgh, and Dublin. There are 16,000 numbered stalls in the Palais de l'Industrie, where the ceremony is to take place, which are reserved for the holders of season tickets, the price of which has just been reduced to sixty francs, whether for ladies or gentlemen. At the entrance of the sovereigns an unpublished hymn, by Rossini, will be performed by a powerful orchestra, with the aid of a large choir and military band. On the 4th of July will commence a series of grand concerts, festivals, and musical competitions in the same building.

Last week the word Vauxhall was used inadvertently in connexion with brown stone-ware. Messrs. Doulton and Watts alone represent the Surrey potteries, and their establishment is not in Vauxhall but in Lambeth adjoining.

Commerce.

SUGAR FROM STARCH.—"An interesting fact has been communicated to us," says the *Journal des Fabricans de Sucre*, "by one of our correspondents in Canada, viz., contrary to the results obtained in the United States, effected at Montreal the complete conversion of starch of maize and of cellulose into sugar. Little bitrinite and strong crystals were obtained. There was a large quantity of this maize sugar manufactured at the Molson's refinery, in New York, last year, and crystallized with cane sugar, and delivered to the trade with no complaint, or the slightest suspicion that it partly consisted of sugars manufactured from cereals. A portion has been taken out in Canada, and another in the United States, and the inventor is actively engaged in following up this curious discovery, which, if successful, will add another to the different sources of sugar production." On this the *Produce Markets Review* observes, "It may be visionary on our part, but we cannot help thinking that the manufacture of crystallizable sugar from starch is one of the great chemical discoveries which in some day or other revolutionize commerce. We shall then be dependent neither on the beet nor on the cane, but every country would be in a position to manufacture sugar from almost all vegetable products. The trade in potato or starch or glucose sugar is already a large one in Germany, and if the sugar could be crystallized, development would be vast."

Colonies.

SALMON IN AUSTRALIA.—The *Times* correspondent at Melbourne, in a recent letter, says:—"We have news from Dr. Officer, the Speaker of the Legislative Assembly of Tasmania, who takes the liveliest interest in the naturalization of useful animals in Australia, a letter informing us that he has himself seen a considerable number of salmon in the Upper Derwent, the fish having escaped the grisle state of growth, and, obedient to their instinct making for their native river, the Plenty. It would be difficult to give you any notion of the interest this subject has excited in the sister colony. I was on a visit there a few months back, at which time the intelligence portion of Tasmanian society were divided into two parties—those who expected and predicted, and those who did not expect, and, therefore, did not predict, that the salmon would return from the sea to the river in which they were hatched. They have returned, however, in force; and Mr. Frank Buckland may add this instance to his list, as the grandest achievement effected in the naturalization of fish among all other new enemies, and exposed to other new conditions of existence."

HARVEST IN TASMANIA.—Tasmania, like the rest of the Australian colonies, has this year been blessed with an abundant harvest. It is stated that many farmers will have two or even three bushels of wheat where formerly they only got one. But the lowness of price of wheat this year is looked upon as a drawback, and the Victorians have imposed a duty of 9d. per cwt. on the grain, and 1s. per cwt. on all flour imported into the market. Of both these things the farmers complain greatly.

RAILWAYS IN NEW SOUTH WALES.—The Southern line is now the longest continuous railway in this colony, but it appears that, as in the mother country, extensions have not been followed by the anticipated increase of traffic, and, of course, therefore, the additional outlay has been, to a great extent, a dead investment, imposing annually an increasing burden on the revenue of the colony. The railways have not monopolised the traffic of the highway, and even if they had it seems doubtful whether the traffic would have yielded net profits enough

y a full dividend. It is remarkable how slightly passenger traffic has increased with the extension of railways. In 1861, 72 miles were open for traffic, the number of passengers was very nearly 600,000. In 1864 there were 142 miles open, that is, nearly double previous length, but the number of passengers only ased by one-sixth. The goods traffic in the same val showed a far greater rapidity of increase; it more than trebled, and not far from quadrupled.

Notes.

BARONAUTICAL EXPERIMENTS IN FRANCE.—M. Camille Flammarion, who has undertaken the conduct of these experiments under the Scientific Commission, has made ascents, in one case confining his observations to zone, between 500 and 800 metres in altitude, and in other attaining the greatest possible height under circumstances at daybreak. In the latter case, in order to avoid all extra weight, M. Flammarion recently ascended alone from Barbison, a village on the confines of the forest of Fontainebleau, at ten minutes to noon. At first the humidity caused the balloon to rise slowly, but as the sun rose the ascensional power increased. The sky was perfectly clear, and in an hour the altitude attained was 1,000 metres; at 5.30 it risen to 2,000 metres; at 6 to 2,400 metres; at 6.45 3,000 metres; at 6.47 to 10,000 feet. The difference in amount of humidity in the air was very remarkable; at 120 metres above the surface the hygrometer indicated at 98°, whereas at the greatest altitude reached it marked 25°. This excessive dryness, together with rarefaction of the air, produced a painful sensation in the lungs and ears. The descent was made without slightest accident.

RAILWAY EXCURSIONS ON THE CONTINENT.—The Northern Railway Company of France and the directors of the German lines have made arrangements for a direct service, to carry passengers in one day between Paris and Frankfurt-sur-Main, by Metz, Forbach, Reims, Creuznach, and Mayence, without change of carriages. Monthly tickets will also be delivered for the same journey. This service will correspond at Paris with the trains for Wiesbaden, and at Frankfurt with those of Soden, Hombourg, and Naheim.

Correspondence.

PORCELAIN.—SIR,—On my return from Paris my attention was directed to a remark in Mr. Chaffers's most interesting lecture, published in your *Journal* of 24th ult. page 435 he says, referring to the Paris Exhibition, "only two manufacturers of porcelain have exhibited (Sèvres and Copeland). I beg to say that Worcester is represented; but the specimens are so few that I can hardly understand their being overlooked. Still, I value these few pieces as of such a character as to uphold the reputation of the manufactory. They have already obtained high praise. It is with much diffidence that I offer an opinion which is at variance with what is expressed by so experienced an adept as Mr. Chaffers, but I must protest against the porcelain recently exhibited at South Kensington, and called 'softest,' being ascribed to any European manufactory. There are a few pieces in the cases which are undoubtedly 'softest,' but they are very different from the great majority of the specimens. Mr. Chaffers is a high authority in porcelain fabrics, but, as a potter, I assert that the porcelain exhibited is Chinese, and the painting Chinese also. The decoration of some Chinese porcelain is such that it must have been imported in a white state and painted in various manufactories of England and the Continent. There are a few pieces of this character in the 'softest' cabinet. In the Marquis D'Azeglio's collection

at South Kensington, there is a tea or coffee set of Chinese porcelain with European painting. I have also sent from Worcester a Chinese cup and saucer with a Worcester print on it.—I am, &c., R. W. BINNS.
Royal Porcelain Works, Worcester, June 18, 1867.

FLAX MACHINERY.—SIR,—It was not until last week that a friend called my attention to your *Journal* of 29th March last, containing the report of a paper read by Mr. C. F. T. Young, on flax and its preparation, &c., in which there is a description of a flax-breaking machine, said to have been the invention of Mr. Brasier. This invention is mine, and was patented by me in 1862. The specification of my patent, dated 8th November, 1862, No. 3015, clearly shows this to be the case. Mr. Young, in his paper (page 296 of your *Journal* for March 29th), says: "The machine (Mr. Brasier's), as you will observe, consists of one large fluted cylinder, or roller, on which work four small rollers, also fluted, resembling somewhat in this respect the construction of the cotton carding engine." My provisional specification contains the following:—"My machine consists of a fluted roller, mounted on a frame or carriage; on the top of this roller I place one or more smaller rollers, either fluted or smooth." And my claim at the end of the complete specification contains the following words:—"What I claim is the use of an oscillating or rotary frame, carrying upon it one, two, or more rollers, which said rollers have a motion of rotation round their own axis," &c.; and the drawing shows the machine clearly to be the same as claimed by Mr. Brasier. My specification states that "The machine in Fig. 3 shows an application of the invention for the purpose of breaking and softening flax, hemp, grapes, or other vegetable fibres to be used for textile fabrics, by altering the surface of the rollers, or cylinders, so as to be either smooth, grooved, corrugated, serrated, or waved," &c. The only difference between Mr. Brasier's machine and mine is, that in the latter "two beaters" are added. For the last 20 years I have been engaged in India and this country in practically experimenting on flax, reed grass, and other fibres, and my breaking machine has been proved to be the best ever invented. Permit me to add that the Mr. Brasier alluded to in the paper derived whatever knowledge he possesses of the machine from me. In the year 1863 he was in frequent communication with me, and certainly knew nothing of the machine then beyond what he gathered from me, whereas several machines were made for me in 1863 by Messrs. Fairbairn and Co., of Leeds, and sent to Calcutta for breaking reed grass and other fibres. I trust you will allow me to set myself right with the public, and to vindicate my claim to be the inventor of the fluted roller flax-breaking machine, described by Mr. Young as the invention of Mr. Brasier. I may add that this is the fifth flax-breaking machine I have invented and patented.—I am, &c., HENRY GARDNER.

13, Laurie-terrace, St. George's-road, Southwark.

MEETINGS FOR THE ENSUING WEEK.

GRANTS OF PROVISIONAL PROTECTION.

- Apparatus for travelling through the atmosphere and on land and water—1525—J. M. Kaufmann.
Baths, marine—1450—G. F. Harrington.
Billiard tables—1440—A. V. Newton.
Boilers—1497—V. Barford and J. Skerman.
Boilers—1584—E. Pollitt.
Boots and shoes—1545—G. M. Wells.
Calculating apparatus—1470—C. E. Brooman.
Cast steel, manufacturing—1649—C. Sanderson.
Castors—1619—J. Cartland and H. Bold.
Cutlery, sharpening—1491—A. M. Clark.
Engines and pumps—1529—E. W. Hughes and T. H. Head.
Fabrics—1501—J. Owens.
Fabrics—1556—A. M. Clark.
Fabrics, machinery for removing the card boards, &c., from the folds of—1430—J. C. Ellison.
Feed-water apparatus—1538—A. V. Newton.
Fire-arms, breech-loading—1446—C. Robert.
Fire-arms, breech-loading—1521—W. J. Murphy.

Flax, &c., cutting—1507—W. Nichols, J. Burnley, T. Wilson, and G. Jackson.
Fluids, measuring—1561—H. and H. Frost.
Food for sheep, &c.—1598—W. Mitchell.
Furnaces—1454—J. M. Stanley.
Furnaces—1495—J. G. Tongue.
Furnaces—1517—D. Adamson.
Furnaces—1637—C. E. Brooman.
Furnaces—1558—W. Dutton.
Furnaces—1559—W. P. Struvé.
Furnaces—1574—W. Coulson.
Gas blow pipes—1530—F. H. Johnson.
Granaries—1527—A. Martin.
Granite, &c., artificial—1458—P. M. Parsons.
Harvesting machines—1568—J. C. Mewburn.
Horses, feed bags for—1395—J. A. Knight and C. Barstad.
Liquids, injecting and ejecting—1513—A. Barclay.
Locomotives, tenders for—1347—G. Kraus.
Lubricators—1523—W. Brookes.
Malt, drying—1486—J. L. Norton.
Mowing machines—1499—W. M. Cranston.
Mustard, appliances for serving—1552—J. M. Napier.
Paraffin oil, &c., burning—1487—T. Metcalf.
Photographic pictures—1563—J. Simpson.
Pipes, coupling—1560—H. B. Barlow.
Pipes, seal or dip—1878—H. and F. C. Cockey.
Printing from plants, &c.—1432—H. C. Baldwin.
Printing machines—1444—J. Harper.
Railway buffers—1543—C. Martin and J. Grint.
Railways—1442—G. Coles, J. A. Jaques, and J. A. Rankine.
Railways—1511—W. F. Henson.
Root-cutting machines—1535—E. Howell and T. Hardy.
Screw propellers—1567—W. H. Whettem and E. Walker.
Sewing machines—1551—G. T. Bondfield.
Ships, apparatus for indicating and registering the size of water in the holds of—1239—M. A. F. Mannons.
Ships, &c., construction of—1434—F. Bonney.
Shoe for piles—1460—H. Hollingsworth.
Signals, &c., railway—1379—R. Andrew.
Spectacle frames—1541—H. Blackham.
Steam generators—1547—A. M. Clark.
Tea pots, &c.—1567—W. Ryland.
Telegraphic instruments, &c.—1531—M., R., and M. Thellier.
Telegraphs—1566—P. A. J. Dujardin.

Journal of the Society of Arts.

FRIDAY, JUNE 28, 1867.

Announcements by the Council.

VISIT TO THE PARIS EXHIBITION.

The Council have directed the Secretary to make arrangements for a visit of the members of the Society to the Paris Exhibition. The period for this visit is not yet fixed, but it will probably be towards the latter end of July.

ARTIZANS' VISITS TO PARIS.

The following is the list of subscriptions up to the present date:—

SUBSCRIPTIONS.

The Midsummer subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

SIXTEENTH ANNUAL CONFERENCE.

The Sixteenth Annual Conference of the Representatives of the Institutions in Union and the Local Educational Boards with the Council of the Society, was held at the Society's House on Wednesday, the 19th inst. The Right Hon. HENRY AUSTIN BRUCE, M.P., presided.

The SECRETARY having read the annual report to the Council of the Society, which appeared in last week's *Journal*,

The CHAIRMAN said, before entering upon the discussion of the subjects suggested for the consideration of the Conference, it would be convenient to know whether gentlemen had any observations to offer with respect to the time for the final examinations, or whether the time as usually fixed was generally found to be convenient.

No observations being offered,

The CHAIRMAN requested the Conference to proceed with the consideration of the first subject on the agenda, viz.:

WHETHER THE MEANS AT PRESENT AVAILABLE FOR THE PROMOTION OF PRIMARY EDUCATION ARE SUFFICIENT TO QUALIFY THE WORKING CLASSES TO TAKE ADVANTAGE OF THE SECONDARY INSTRUCTION OFFERED BY INSTITUTES TO ADULTS?

Mr. HARRY CHESTER said, as he had put this subject on the list, he might be permitted to commence the discussion of it by moving a resolution replying to that question in the negative. Having taken great interest in these examinations from the commencement, and having, with one exception, attended every Conference, he was happy to say the report presented on the present occasion was, in his opinion, the best they had ever received. The increase of the number of candidates, both in the elementary and final examinations, and the improvement in the character of the work done, were causes for congratulation, and he thought they had great reason to be satisfied with the work which the Society of Arts and the Institutions in connection with it had now been engaged in carrying out for a period of eleven years. They must, however, all be struck with that which appeared in the reports of the visiting officers of the district Unions—that which had long been apparent to his mind, and, no doubt, to that of the right hon. chairman, who had such a perfect knowledge of the subject of national education—viz., the great difficulty which all the Institutions had to deal with in affording secondary instruction, in consequence of the lamentable deficiency of the means of primary education throughout the country. Doubtless there was in many places an admirable system of primary education at work (for he believed the system of schools under the Committee of Council on Education, as far as it went, was as good as it well could be), yet it had no effect over a large part of the country with respect to children over the age of ten years, and the consequence was, that that which they gained at school was very soon lost, and the great bulk of the adult labouring population were totally unable to read and write. There had been controversies of late in the public journals upon the question whether the statements which had been

made as to the lamentable deficiency of national education were exaggerated or not. He did not hesitate to say he believed it was almost impossible to exaggerate the lamentable deficiency which still exists, and he thought this meeting, though not called upon to enter into the discussion of the general question of education, ought not to separate without an expression of opinion that the means of primary education were insufficient for their particular purposes. The resolution he begged to submit was as follows:—

"That the means at present available for the primary education of the working classes are not sufficient to qualify them for the receipt of secondary instruction in any localities where there are not voluntary promoters of schools who possess the amount of zeal, liberality, and pecuniary ability which are required to secure grants from the Parliamentary fund; and that, to provide adequately for the education of the working classes in general throughout the kingdom, the attention of Parliament should now be directed to the best means of dealing with the whole subject of national education."

This resolution referred to one of the most difficult questions of the day, that of compulsory education, a question which was, in fact, two-fold, first, whether they should compel property in particular localities to provide the means of education, and secondly, whether they should also compel parents to send their children to profit by those means when so supplied. He did not propose to touch the latter part of the resolution, but he believed public opinion was ripe to the idea that wherever there was property and a population there the means of education ought to be provided. His proposition did not tend to disturb existing arrangements, but where these arrangements failed, he submitted that Parliament should provide some other means of dealing with the question.

Mr. F. WOOD (Walworth Literary and Scientific Institution) seconded the resolution, and expressed his concurrence with all that had been stated by Mr. Chester. He said in the Institution he represented, the attempt to establish classes for subjects not amusing or gratifying to the personal vanity of the members had been a failure. Class after class had been formed and had died away; but of the large number of members of the Institution he believed there were not more than four working men properly so called, and no inducements that were held out had the effect of adding to the members from that class of society. Lectures of a scientific nature were very thinly attended, while on occasions of musical entertainments or lighter amusements the hall was crowded. He believed the feeling of the country to be in favour of providing a remedy for the wide-spread ignorance which prevailed among the labouring classes of the kingdom.

Dr. WATTS (Lancashire and Cheshire Union of Institutions) considered the resolution was drawn too mildly. It was certain nothing could be more true than the assertion that the means at present available for the primary education of the working classes were not sufficient to qualify them for the receipt of secondary instruction in any locality where there were not voluntary promoters of schools who possessed the amount of zeal and liberality required to secure grants from the public fund. Nobody could doubt that. He went further, and said they had not primary education enough, even in the localities where the parliamentary grants were given, to enable the youth of the country to get the secondary instruction which the Literary Institutions were intended to supply. He particularly called attention to the report of the visiting officer of the Lancashire and Cheshire Union, and to the fact stated in that report that of the Lower Grade candidates 489, out of a total of 602, had attended day school for an average of 5·5 years, and had left school for not more than an average of 2·8 years, all of whom failed to pass the Lower Grade examination, which only included the rudiments of arithmetic, British geography, and of English history.

Mr. H. H. SALES (West Riding Educational Board) said this examination corresponded with Government grade, the other subjects be

Dr. WATTS went on to remark if this were the case amongst pupils of the Lower Grade in those Lancashire Institutions where they received more than five years day-school instruction, he was not wrong in saying provision for education where Parliamentary grants were given was not sufficient to qualify them for the secondary instruction they wished to give. The Educational Society of Manchester had made searching examination throughout Manchester and Salford, and the result had been to show that more than half the children of that age were neither at school, nor at work; and further, that three-fifths of the absentees were unable to pay anything whatever for school fees. To enable them to pay of this by the standard which was set up, he might say that the society to which he referred assumed that wherever the income per head per week, exclusive of rent, was three shillings, these people could start to pay for their instruction; but in the case of more than half the absentee children, it was found that the weekly income was less than three shillings per head, exclusive of rent. Therefore, nothing less than free schools with powers to compel attendance at school, would be primary instruction for that class of the population. Even in the case of Manchester and Salford, which received a share of the parliamentary grant, there could be no hesitation in saying the provision for primary instruction was very insufficient, and he suggested as the resolution should be altered to this effect—"That the attention of Parliament should be directed to the best means of dealing with the whole subject," instead of "those localities where such zeal and liberality did not exist;" and with that alteration he should support the resolution, because the time was come when it was absolutely necessary we should look to a national system of education; and he believed a national system of education was impossible unless it provided for free education upon a right basis, with local management and government supervision. Adopting those principles, he was passing some such bill as the right hon. gentleman had now before the House, which was a permissive bill, and which, if passed, would be adopted by Manchester and Salford, so as to give some experience to the country generally,—if some such bill were passed, they could look forward to nine or ten years of progress, and by that time they would have, probably, an efficient national system of education. He should not oppose the resolution even if the alteration he suggested were not adopted.

Mr. CHESTER expressed his willingness to adopt the alteration suggested by Dr. Watts, adding, that he expressed all he thought and felt on this subject he should propose a much stronger resolution.

Lord LYTTELTON (South Staffordshire Association) would support the resolution. He thought the merits of the resolution were, in the first place, that it was mildly expressed, and in the next place it did not go into particular details. The present subject was one of a general character, and so was Mr. Chester's resolution, which made him the more able to support it, because he could not entirely agree with some of the strong arguments that had been made in treating this question. Mr. Chester said he had not put the case half strong enough. They might agree in the practical course to be adopted on this and other questions without agreeing to the facts and conclusions of those who brought them forward. He did not deny positively what had lately been stated—that there were in London 150,000 children uneducated. That might be so, but he submitted it was utterly unproved by the method of investigation which was pursued. He believed that method had been pursued not only on this subject but on others, and it involved such obvious fallacies that it was inconceivable how it obtained such general currency. He took it that this investigation was made on the same plan as a general or police investigation was made with regard to the attendances at church. They went on a given day, and found a number of children who ought to be at school and were not, and they put them down as uneducated.

If they were not at school on Monday they might be on Tuesday. What ought to be done was an investigation by the clergy from house to house, not to ascertain a fact at a given moment, but to ask, "Does that child go to school, or has it ever been to any school?" At the same time this did not affect the practical question before them, for it could not be denied that the education received was insufficient. But when Mr. Chester said he had not spoken strongly enough, he (Lord Lyttelton) said that when they were told that below a certain station the whole population were unable to read and write, he believed such statements utterly fabulous. He did not doubt they were unable to read and write as well as they ought, and could do neither without painful exertion; and this ought to be remedied. He could not say it did much good to give such general statements as these. So also with regard to the inability to pay, adverted to by the preceding speaker. He (Lord Lyttelton) doubted whether that was the case except with more than a very few, and, literally speaking, it was impossible it could be true in the present state of the law. The Act known as Denison's Act existed, and it was in the power of the boards of guardians to ascertain which of every one of the population had not their children at school, and which were literally unable to pay.

The CHAIRMAN—They must be receiving out-door parish relief.

Dr. WATTS said there was this difficulty; when the parents ceased to receive out-door relief, unless the children were sent to school the Guardians were liable to surcharge; and because of that surcharge they took no interest in the Act.

LORD LYTTELTON—That was quite true; but see on what a narrow edge they balanced the question. There were vast numbers of people just able to pay their way, except twopence per week, and we must always consider education one of the necessities of life; and if the means of the parents were so extremely narrow the question was whether the allowance should not be increased, to the extent of enabling them to pay the small school fees. It seemed to him, while they agreed in the general conclusions stated in the resolution, the practical remedy consisted in some form of compulsory education. There were many ways of applying compulsory education; and rate-paying was one. Some years ago, in a pamphlet which he wrote, he asserted the principle of compulsory education, and it had given him satisfaction to see of late years public opinion was coming round to that view. When he gave evidence before the Duke of Newcastle's Commission, after he printed that pamphlet, he saw that public opinion was going in an opposite direction, and that the feeling in favour of compulsory education was dying out; but it had revived within the last few years; and he hoped they would keep the principle in view, that it was a part of the duties of citizenship that the education of the people should be in some manner secured and provided; and this, he apprehended was the principle advocated by the author of the resolution, and as such he should support it.

Mr. JAMES HOLE (Yorkshire Union of Institutes) had frequently heard doubts as to the extent of ignorance expressed by those who were not familiar with the habits of the poor in large towns. He had heard the strong facts stated with regard to the town of Leeds disputed, when he recommended that the simple test should be applied of taking a cab and canvassing for themselves whether what was stated was not true. If the noble Lord who had just spoken would honour Manchester or Leeds with a visit he could soon be convinced of the accuracy of the facts stated by Dr. Watts. As hon. secretary of the Yorkshire Union he could state, with reference to elementary education in Mechanics' Institutes, that in his Union, which comprised 24,000 members of Institutes, of that number one-third attended evening classes, and the large majority of them were doing the work which ought to have been done in the primary schools. There were but few of the Mechanics'

Institutions engaged in secondary instruction, and the young men were struggling with difficulties in the Mechanics' Institutions which ought to have been surmounted years before. With reference to the powers of Boards of Guardians, he spoke to the clerk of a Board in Leeds and asked him why those powers were not enforced. The reply was that it was the cause of a great deal of ill-feeling, and practically the powers were not enforced. It was true by law the guardians could compel the children of a parent receiving relief to be sent to school, but it was practically inconvenient to take this course, and the law was a dead letter. He fully endorsed the facts stated by Dr. Watts, and was well acquainted with the districts examined by the Educational Aid Society in Manchester.

The CHAIRMAN begged to inquire whether the examination into the state of education among the lower classes in London was made in the manner described by Lord Lyttelton, or whether the clergy made a return of the number of children on their books?

Rev. JOHN OAKLEY (Metropolitan Association) said with reference to the type and standard of primary education, the startling facts of the fewness of the number of children that would pass even the sixth standard of the Government examinations had been twice brought under the notice of the House of Commons; and when that standard was deliberately drawn at a point to represent the minimum of education, it might be taken for proved that the deficiency of primary education was so great that the work of the Institutions was in a large degree directed to elementary instead of secondary instruction. His own experience as a member of the Council of the Metropolitan Association quite confirmed that statement. He found children who had been five years at school making the most flagrant errors in spelling. With regard to the method of investigation, which gave the result of 150,000 totally uneducated children in London, to which the noble lord took exception, he (Mr. Oakley) would state that the clergy were furnished with a series of questions, the replies to which no doubt, in many cases, were in a great measure guessed at; others, he knew, made the most careful investigations, such as Lord Lyttelton had described, from house to house, and their inquiries embraced other than Church of England schools. In many cases the returns were most full, while others, no doubt, were the result of haphazard estimate; and looking at the deficiency of primary education he did not think it was too much to infer that those children who were absent from the schools were practically wholly uneducated. He firmly believed that London's contribution to that class would exceed 150,000.

Mr. H. H. SALES said no remark from him was needed to strengthen the statements already made, that the means available for primary instruction were not sufficient to enable them to conduct the Institutions properly. As the representative of the West Riding Educational Board, he would say that, in his opinion, nothing did so much injury to education as conclusions drawn from statistics respecting the state of education in the country. It did not matter whether there were 100,000 or 200,000 uneducated persons in their midst, for seeing the state of education with their own eyes, they could not but arrive at the conviction, without statistical tables and reports, but by merely going amongst the working classes, that in the matter of the primary education of the people they were doing very little at the present time. Seeing how much the work of the Institutions was thwarted and hindered by the low state of education of those who attended the Institution classes, they wanted no statistics to assure them that the state of primary education with regard to the labouring population was lamentably deficient, and the work would not progress till the nation took up the question of primary education with greater earnestness than it had ever yet done. He cast no reflections upon the Committee of Council. To them they were indebted for the excellent

scheme of education now in force. But they wanted more than that. It did not touch the lower population to the extent that was required. They could not succeed until the primary schools were in a far more efficient state and better attended than they were at present. This led him to the remark of Lord Lyttelton, questioning the statement of Dr. Watts with regard to the inability of people to pay for education. It was not so much a question of inability to pay as of disinclination to pay. There were many people earning large wages who did not see any advantage arising from educating their children. Therefore, they must not go upon the question of inability to pay, but rather upon that of indisposition to do so. Those who brought children into the world should not be permitted to allow them to grow up as pests of society. They must set about remedying the evil, until people no longer came to the Institutions saying, "Teach us, for we have yet had no education in primary schools."

The CHAIRMAN said in reference to the question of educational statistics, when they found there were 150,000 children in London, and 55,000 in Manchester, not at school, it settled very little; because, as they took the age of nine years, it was possible that some of them might have been at school for some portion of that period. But there was a better test than that, viz., how many they found at a given time on the books of the schools? They were told, in populations in which the working class bore the ordinary proportion, if they found less than one in six upon the school books, then there was a deficiency of education. Tested by that gauge, Manchester had one in eleven; it was clear, therefore, that that city had half as many children at school as it ought, and that was the result of a very minute investigation made there. Some time ago an investigation was made in the town of Merthyr Tydvil, with a view to supply school accommodation for 1,000 children. One district of the town was better provided in respect of schools than the other. It was found that in the Dowlais portion there were 16,000 children, and that school accommodation existed for 2,600, with as good average attendance as possible. He had himself charge of a school in a locality where the population was 7,000. He was quite dissatisfied with the attendance there. He knew there was a vast number of children between nine and ten who were not at school, the parents being tempted by high wages to send them to work; yet there were 1,024 children at the school, or 1 in 7. He was dissatisfied with that, and hoped to improve it. Taking another part of Merthyr Tydvil, exclusive of Dowlais, there was a population of 41,000; he found there only 3,200 children were upon the school books, whereas it ought to have been 7,000, or 1 in 6 instead of 1 in 13. As to the question of ability to pay, he thought Lord Lyttelton had omitted to observe that between ability to pay and absolute pauperism there was a large margin; and it was not a question of mere ability to pay, but of ability to do without the wages which the children would earn, for these were the great temptation to send children to work. He was not one of those who thought compulsory education could be immediately applied. They were about to extend the provisions of the Factory Act to many other employments, which would have the effect of bringing a large additional number of children into the schools, but the work must be progressive. He thought they were travelling as fast as they could fairly do, but he was of opinion that the system of the Privy Council, which, however, was not the system of the Privy Council itself, but the system which they were empowered by Parliament to carry out, that system was at this moment not only inadequate, but nothing could make it an efficient system of education for this country. Another experiment had been proposed, and would probably be tried, for he believed it was impossible for Parliament to reject the propositions now before them without offering the same time some alternative. He hoped this re-

solution would be carried by the meeting. He did not believe there was any exaggeration in the language used by Mr. Chester. It would be remembered that the report of the Committee on Education stated that only 1 in 4 of those educated in the best primary schools could read and write satisfactorily; and it might fairly be assumed that more than half the population were unable to read and write to any useful degree. They had an immense task before them. At present they had not the machinery, but it would have to be provided, and provided by the State.

Mr. CHESTER said he need not offer any observations in reply, as they had a general concurrence of opinion in favour of the resolution. He had not pretended to say what Parliament should do, but he was not satisfied with what Parliament had done. They must do more to provide for the education of the people of this country.

Mr. F. REYNOLDS (City of London College) wished to support all Mr. Chester had said. For many years he had been connected with educational work, and had acted as examiner for three Local Boards, and his experience of primary education was that it was most unsatisfactory.

Rev. J. S. BARROW (Ryde Philosophical and Scientific Society) would say one word in defence of the schools aided by government. He thought they had been unfairly spoken of. As the result of his own experience of twenty years in elementary schools, he would say any child who attended those schools regularly from six to ten years of age would not only be able to read and write fairly and well, but would also have acquired a sound substratum of knowledge. He was not prepared to say one word with regard to the mass of the people being without education, but he would say that did not affect the character of the education already provided, inasmuch as he believed it to be, as far as it went, excellent. Mention had been made of the deficiency of primary education in those who presented themselves for the Elementary Examinations of the Society. That was probably true, as they left school at 11 years of age, and there was a blank between that and 15 which they could not fill up.

Mr. THOMAS LAWTON (Lancashire and Cheshire Union of Institutes) said in his Union there were large numbers of children out of the schools in a state of educational destitution; but there was also another point:—They had a large number of children at school with whom the masters found difficulty, because there was no provision made, except in the colliery districts, to check the admission of children on the "half-time" system. Schoolmasters had told him if there was some regulation of this kind,—that no child should be allowed to go on the half-time system without first obtaining a certificate of the second or third standard, they would get on better. He believed the extended operation of the Factory Act was doing a great work in this direction; and he anticipated great advantages from the half-time system, the scholars being first certified up to a certain point.

The CHAIRMAN observed that Parliament had never gone so far as to say that no child should be allowed to work who could not read and write; but with reference to the colliery population, children between ten and twelve years of age were not allowed to work if they could not produce a certificate that they could read and write, or that they had attended school a certain number of hours per day.

Mr. LAWTON believed the colliery masters were instructed not to accept any children without such certificate.

Rev. JOHN OAKLEY subscribed to a large extent to the remarks which had been made in disparagement of statistics, but he did not think, while other statistics were held to be fallacious, those of the Royal Commissioners should be taken as infallible. He thought they were equally open to criticism.

The CHAIRMAN remarked that the National Society, in

their annual report, adopted the figures of the report of the Royal Commission presided over by the Duke of Newcastle. He considered that report was one of the most valuable documents ever issued on the subject of education; but its weak point was always known to be its statistics, and he was afraid the National Society in their report relied to a great extent upon the same calculations as had been supplied to the Royal Commissioners. The statement of the Royal Commissioners was that there were some 120,000 children who might be regarded as never having entered a school, and they said of those who had been to school for any time there was 1 in $7\frac{1}{2}$ of the population. That settled nothing, because the question was, how much time had been passed at school? If 1 in $7\frac{1}{2}$ had been at school only for a few months, practically they might as well not have been at school at all. After a great deal of examination he felt that the statistical tables of the Royal Commissioners were the only part of their report not worthy of confidence.

Mr. LARKINS (Metropolitan Association), with regard to the statistics, desired to confirm what had fallen from Mr. Oakley. With regard to the inability to pay for education, he believed that was the grand reason why the state of education was so low. It was found amongst 100 members of a Working Men's Club at Westminster that 50 could neither read nor write. They were so poor that they could not afford a halfpenny per week for their own education. What, then, must be the state of the case with regard to the children of those people? The lectures given to working-men in Lambeth last year, through the instrumentality of Mr. Twining, brought together on some occasions as many as 1,500 people; and he found that fully two-thirds of the men attending these lectures were utterly unable to read or write. He thought the remedy which was proposed, in the shape of evening classes, might possibly be, to a certain extent, the cause of the disease in some cases, because it was said by the people they could send their children to work in the day, and at the age of twelve they would attend the evening schools, and thus up to that age all primary instruction of the children was neglected.

Mr. ALEXANDER CRAIG (Glasgow Institution), on behalf of the large and important centre which he represented, expressed a hope that full force would be given by the Conference to Mr. Chester's resolution.

Mr. MARCUS (Worcestershire Union) suggested an alteration in the wording of the resolution. It did not, he said, imply what they were aiming at. It implied that the education now given in the National Schools was not sufficient for the purposes of the Institutions.

The CHAIRMAN remarked it rather implied that the application of the means was insufficient. It was not said that the schools already provided were not sufficient.

Mr. MARCUS apprehended it was not that the schools were not sufficient, but they wanted to bring a larger number to avail themselves of them.

The CHAIRMAN then put the resolution, which was carried unanimously.

WHETHER PROVISIONS SHOULD BE INSERTED IN THE MANCHESTER EDUCATION BILL, NOW BEFORE PARLIAMENT, WHICH WOULD AUTHORISE GRANTS TO BE MADE TO EVENING SCHOOLS AND CLASSES?

Mr. CHESTER said he felt some diffidence, in the presence of the right hon. chairman, who had introduced this Bill into Parliament, in describing its provisions; but reading the Bill, it struck him that it excluded everything in the nature of evening schools from participation in the rates, to raise which powers were given. If he was wrong in this idea he would withdraw the subject; but he understood the Bill to provide that no grant was to be given in respect of the attendance of persons at schools after five o'clock in the afternoon; and if that were so, it excluded all evening schools and classes. He hoped the time was come when it was admitted that evening instruction, by means of classes,

was not a mere ornamental and accidental addition, but an essential part of education. He had expressed his views on the subject in the following resolution, which he would simply commend to the favourable notice of the Conference:—

“That, as the demands of labour make it impossible that the children of the working classes shall be retained at day schools until their education is complete, and as their attendance at evening classes is essential to the completion of their education, this meeting is of opinion that, in any measure which Parliament may pass for authorising the support of schools by local rates, provision should be made to include in such support the classes for systematic instruction in evening schools and institutes.”

The CHAIRMAN, having read the resolution, said he would ask Mr. Chester whether he limited the application of the rates to payment for children in the night schools?

Mr. CHESTER replied he did not limit it to children. He thought wherever there was provision for education, those means ought to be applied to adults as well as children. He would mention the City of London College and the London Mechanics' Institution, than which, he would venture to say, there were no schools in the country which were doing a more important work in education.

Mr. SALES having seconded the resolution, and expressed his concurrence with what had been said by Mr. Chester,

Dr. WATTS said, admitting the principle laid down by Mr. Chester, the question in his mind was whether the introduction of a clause into the Bill, extending the grants to evening schools and classes, would not endanger the Bill itself. If it was the opinion of the chairman that it would do so, he would ask Mr. Chester to withdraw the resolution. This was a question in which he thought they should be guided by the judgment of the chairman. For his own part, he thought that when youths reached the age of (say) 14 they ought to be at work, and for those who were at work it seemed preposterous to levy a rate to pay for their education.

Mr. CHESTER remarked he had never proposed that the education of adults should be given to them altogether gratuitously, but only that they should not be absolutely excluded from assistance from the rates.

Dr. WATTS objected to that on the same principle, because he thought when people were at work they could and ought to pay entirely for their education, and if they once introduced the principle of paying for those who were earning wages he did not know where they would stop.

Mr. CHESTER said they assisted the education of the higher classes in the Universities; why should they not assist these poor people? Under some circumstances even at present Government gave aid to night schools.

Dr. WATTS was aware there were exceptional instances made by the Privy Council in which aid was given to evening schools, but he believed the Privy Council had since done all they could to lessen that aid. If Parliament deliberately adopted this principle he had nothing more to say, but he repeated his opinion that where people were earning wages they should pay for their instruction, and they ought to be earning wages at the age of 14 if they belonged to the working class. If the chairman thought, with such limits, the introduction of a clause of this nature would not endanger the Bill, he (Dr. Watts) would be in favour of it.

The CHAIRMAN admitted that the Privy Council had been somewhat illogical in the principle adopted in aiding night schools, inasmuch as it excluded the aid to a number of persons who were of an age to pay for their own education. In the opinion, he thought, of the majority of the public, the Committee had been wisely illogical in the course they had pursued. His own impression was, if the conditions with regard to the night schools were guarded in the same way as they had been by the Minutes of Council, the introduction of a clause like that proposed would not endanger the Bill. Many persons, both in and out of Parliament,

believed that the merits of night schools were exaggerated. Many others considered night schools good elementary schools, in which those might be taught who could not attend day schools. He thought that was a delusion, but he agreed that night schools were valuable as enabling children to continue their education after they had commenced working. So far from the Committee of Council having restricted its assistance, he was bound to say one of his own acts was to introduce a Minute which was adopted by Parliament, and which facilitated the examination of night schools at the time when they were most fully attended. The result of that had been to increase the payments to night schools, and also to increase the attendance at them. The question was whether the money of the State was well applied in this direction; if it was so, it was a departure from the strict principle which might be justified.

Mr. CHESTER did not wish to endanger the Bill by the introduction of this clause, but his own conviction was it would add to the popularity of the measure. He had always found, in all the Institutions he had visited, the mention of evening classes was most popular. He did not say they should entirely provide for the education of adults, but he wished Parliament to empower the local managers of the locally-raised rates to grant such aid as they might think fit to the evening schools and classes of the locality. There were many forms of encouragement, such as examinations with consequent certificates and prizes, which might well be provided from such sources without having any tendency to pauperise the education of adults.

Mr. J. HOLZ (Yorkshire Union) remarked that no sum which they could obtain from the working classes themselves would be sufficient to pay for their education. At Huddersfield, where the most successful Institution existed, the highest sum paid by working men was 3d. per week, and a larger sum was realised by means of the weekly payments than if they were spread over a longer period. What was the result? It was necessary to raise by subscription £300 per annum, the larger portion being contributed by the manufacturers, to pay the expenses connected with the education imparted in the Institution. Notwithstanding the subscription by the town to the amount he had stated, and the 3d. per week paid by the members, the services of half the teachers were unpaid. Going from a great Institution like that of Huddersfield to the average of night schools, what could be expected from the working youth? In many places the standard of payment was as low as three half-pence or two-pence per week, and he put it to those present whether they could expect to give efficient evening instruction for that amount? He said it was impossible. Agreeing with the principle that the scholars should pay as much as they were able to do, there was still wanted liberal support from the State to make the evening classes efficient. He thought the great defect of the Minute of Council was that it only gave aid to evening schools held in those buildings which were under inspection. That generally closed the matter at once, and to that limitation he attributed the small extent to which evening class instruction was pursued. Until education was more valued than it was at present, they must expect the youth of the working population to be taken away from school at 12 or 13 years of age, and they wanted an attractive system to induce them to continue the scanty education they had received in the day schools. In his opinion one of the most valuable principles of the Bill before Parliament would be to give aid to properly conducted evening classes.

Mr. HOLBURY (Dudley) was able to speak to the success of these schools in Dudley as far as they went, but they were in great want of pecuniary support. There were boys taught in the night schools who ought not to be there, as they attended the day schools. In the evening schools boys were not admitted under the age of 12, and they paid 2d. per week up to the age of 14. Those

payments were obliged to be supplemented by subscriptions raised in the town. He should be glad to see grants made towards the support of the schools in connection with the Institutions.

Mr. LAWTON said the Department of the Council of Council on Education already granted aid to a considerable extent. There were 41 Institutions in the Lancashire and Cheshire Union where the school received payment from the Department. It was in favour of Government aid being extended to evening schools not in connection with day schools under inspection.

The CHAIRMAN remarked it was a different thing receiving aid from a central fund and receiving it from a local source. It was impossible that a Government ministering a public fund could do so except upon conditions which would secure the efficiency of the teaching. But if the educational funds were administered under local supervision, grants might be made which the state could not be said to make. There was one of the advantages, he thought, of the Bill before Parliament. He then put the resolution, which was unanimously agreed to.

WHETHER, CONSIDERING THE VALUABLE RESULTS OF CO-OPERATION WHICH THE ROYAL HORTICULTURAL AND GEOGRAPHICAL SOCIETIES, AND CERTAIN OTHER COMPANIES, HAVE AFFORDED TO THE SOCIETY IN EXTENDING THE SPHERE OF ITS EXAMINATIONS, LIKE CO-OPERATION CANNOT BE OBTAINED FROM THE AGRICULTURAL AND BOTANICAL SOCIETIES?

Dr. WATTS said, as Chairman of the Manchester Horticultural Society, he believed he could promise such co-operation as they could afford, if they could see any benefit likely to result from it.

Mr. JOHN GIBBS (Chelmsford Literary and Mechanics Institute), as one who had taken some trouble in attempting to promote the study of botany among the working classes, said that though they heard of the valuable results of the co-operation of the Royal Horticultural Society and other societies, he must say they could not congratulate themselves very much on the increased number of candidates which it had produced in the Society's examinations on the subject of botany, particularly. In 1860, before that co-operation was afforded, there were six candidates who passed the examination in botany, two of whom obtained first-class certificates. It seemed difficult to interest the working classes at all in this study; but that the Royal Horticultural and Botanical Societies might be something to promote it he was inclined to believe. From his own experience as a teacher of botany, the class most likely to pay regard to it were those who by their social position were disqualified from receiving the prizes offered by the Society. The special prize to be competed for by gardeners and others was no doubt valuable.

Mr. SALES suggested that this was a subject rather for the consideration of the Council of the Society than the Conference.

Mr. WHITE (Woolwich) recommended the encouragement of cultivation on the allotment system, more especially as the gardens which formerly existed to so large an extent in the suburbs of London were now occupied by buildings.

Mr. H. W. FREELAND had no doubt any definite proposition on the subject made to the Royal Agricultural Society would have the attention of that body.

Mr. CHESTER said he had put this subject on the list with the view that the examinations should be placed on as wide a basis as possible. A year or two ago they obtained the co-operation of the Royal Horticultural Society, which had been advantageous in spreading a knowledge of their system of examinations amongst the gardening class; and last year, through Sir Roden Murchison, they had the co-operation of the Royal

Geographical Society in the subject of geography. It occurred to him, if they could obtain the co-operation of other societies in like manner, the prestige of the examinations would be extended. He was particularly anxious to interest the Royal Agricultural Society in this matter, because they knew that the education of the agricultural population was lamentably neglected. A deputation from this Society was courteously received by the Council of the Royal Agricultural Society, who were good enough to express an interest in this object, but nothing further came of it.

Mr. MARCUS thought the prizes offered in botany especially were not sufficient to induce the study of that science; there did not appear to be any increase in the number of candidates in that subject.

The Conference then proceeded to consider the next subject on the list, viz. :—

WHETHER ANY ADDITIONAL MEANS CAN BE DEvised TO INDUCE THE INSTITUTIONS TO FORM DISTRICT UNIONS, WITH PAID VISITING OFFICERS, IN CONNEXION WITH THE SOCIETY OF ARTS.

Dr. WATTS suggested that the object implied in this subject would be promoted by holding meetings in different parts of the country, where District Unions of Institutions did not exist, at which reports should be presented of the operations of the Unions already established, and a representative of the Society of Arts should attend; this would be the means of forming new Unions, and of bringing more Institutions into connexion with the Society of Arts.

The CHAIRMAN remarked that he had seen the advantages of the Union established in East Lancashire, where a number of Institutions were previously useless for the purposes of education, and existed only for objectless amusement. Since the formation of the Union they had been converted into admirable means of education.

Mr. CHESTER was convinced it only required the advantages of these unions to be known to increase the number of them.

Dr. WATTS proposed the following resolution :—

"That the Council be requested to consider the propriety of sending a delegate to various parts of the country to promote the formation of district unions of Institutes."

The resolution having been seconded and supported by Mr. R. H. Brookes (Banbury Mechanics' Institute), was unanimously passed.

WHETHER ADDITIONAL INTEREST IN THE FINAL EXAMINATIONS MIGHT NOT BE EXCITED BY THE ESTABLISHMENT OF SPECIAL PRIZE FUNDS IN THE DISTRICT UNIONS, TO WHICH SUPPLEMENTARY DISTRICT PRIZES MIGHT BE ADDED BY THE SOCIETY OF ARTS?

Mr. SALES, in introducing the above subject, remarked that a great deal of encouragement in the examinations of the Society rested upon the amount of prizes given in the various localities in which the examinations were carried on, and it was not sufficient that a general prize fund should be instituted for the whole of the country. The various districts were so different one from the other that it was impossible the general prizes given by the Society could influence the whole of the country. It had been found that by giving local prizes a special stimulus was given to the work. In putting this subject upon the paper, he proposed to suggest that they should agree to the establishment in the various district unions of special prize funds for the encouragement of the examinations of the Society of Arts. These prize funds would vary in different districts according to the circumstances of the case. Speaking as Honorary Secretary of the West Riding Board, he might state they were prepared to raise a prize fund for the whole of Yorkshire, because they believed these special prize funds to be of incalculable value; and, having done this, they thought they would be in a position to ask some aid from the Council of the Society—that some special amount might be given to such districts as raised these

special funds. A special examination on religious subjects, on the plan adopted by the Metropolitan Association, had been instituted for the whole of Yorkshire, under the supervision of the Archbishop of York and the Bishop of Ripon, and a special prize fund was raised for the purpose, to which the National Society had contributed £10. They would not ask for a large sum from the Society of Arts for the proposed Yorkshire General Prize Fund, because it was not the amount but the encouragement which they sought for. It might be said the funds at the command of the Council were limited; it therefore was incumbent upon him to show how, without encroaching upon the present expenditure for this purpose, his proposition might be carried out. Looking to the programme of examinations, he was prepared to say there were some subjects which entailed considerable expense on the Society, without making an adequate return. Looking to Navigation, he found in successive years the number of candidates in that subject was reduced from five to one, and the cost for that one candidate was not less than £7 or £8. In Mining and Metallurgy, again, the candidates for examination were very few, and the same might be said for Italian. He was prepared to advance the statement that there were a number of these subjects which it was an injury to them to have upon the list, because it was said in some quarters that they were over-educating the working classes. That cry was always being raised, and it was well, without pandering to popular taste, to avoid everything which gave a colour to that statement. He thought Italian and Spanish might be very well expunged from a system of examinations instituted for the benefit of the labour population. That money might be saved to the Council, and appropriated to special district prize funds such as he had described. He begged to submit the following resolution on this subject :—

"That the establishment of district prize funds increases the interest in the examinations, and the Conference recommends the Council to take the same into consideration, with the view of rendering such assistance as they may deem expedient."

Mr. LARKINS doubted whether these special prizes might not be detrimental to the various other unions. For his own part he did not think money should be voted by the Society otherwise than for the benefit of the candidates in general.

Mr. HELLER (Lambeth Local Board) seconded the resolution, though, he said, he did not approve of the suggestion of the mover of it to aid the special prize fund by eliminating the subjects mentioned from the examinations. This went upon the assumption that the manual labour classes only were to be benefited, whereas he understood the certificates were open to everybody who chose to come up for examination. He thought it wrong to augment the prize scheme at the expense of subjects which the Council had decided to put upon the list. At the same time he hoped the Society might be able to assist district prize funds.

Mr. CHESTER would be glad if something of the kind suggested could be done; but, as a member of the Council of the Society, he could give no pledge that they would be prepared to make grants of money for this purpose. He did not see any essential objection to the proposal provided the funds of the Society were not too severely trenching upon. They knew that grants in aid often had the effect of calling forth large contributions to meet those grants. If the Society did this for one union, however, they must do it for all, and the expense might thus be a serious matter. He should, however, have preferred that Mr. Sales had confined himself to pointing out what should be done instead of speaking of what should not be done. It was to be recollected that the scope of the Society embraced arts, manufactures, and commerce, and though it had given aid to the Institutions in the matter of education, yet there were demands upon it in the interests of art and commerce. The Italian and Spanish languages were necessary to a large number of persons engaged in commercial houses, having trade relations

with Italy and Spain; therefore, though there might be comparatively few candidates, it was of great importance to encourage the study of those modern languages, and he did not desire to see them eliminated from the list; nor did it seem necessary to add that the encouragement of the studies of mining and navigation was of immense importance in such a country as ours.

Dr. WATTS remarked that the importance of district prizes could not be over-rated. In the Union with which he was connected they offered special prizes for essays on various subjects, for drawing, and for examinations in political economy, and the results had been most satisfactory. As to the other point touched upon by Mr. Sales, our trade with South America was rapidly increasing, and the languages of commerce there were Spanish and Portuguese; he considered, therefore, that it would be a great mistake to expunge the former from the examination programme.

Mr. REYNOLDS did not see why the Italian and Spanish languages should be regarded as greater luxuries than French and German. He considered they should be equally within the reach of the persons whom the examinations were intended to benefit.

Mr. LARKINS saw no objection to the principle of the resolution, provided it was extended to all district Unions alike.

Mr. LAWTON supported the resolution. Special prizes in the Lancashire and Cheshire Union had been most beneficial.

Mr. MARCUS observed that he found it difficult to obtain candidates for examination on subjects for which there were general prizes of £5 and £3, extended over the whole of England, Scotland, and Ireland, and on that account he was strongly in favour of extending the system of local prizes.

Mr. SALIS concurred with the last speaker that the feeling of candidates in the provinces was that the larger prizes were almost certain to be carried off by those who were within reach of the superior advantages of the London Institutions; but local prizes would afford a greater incitement to exertion. There might not be much difference between Huddersfield and Halifax, but there was a great difference between the Institutions in the north and those in the south of England. The members were of a different class. In the south a large number followed the occupation of clerks, whereas in the north the bulk of the members was composed of the manual labour and really hard-working class, whom it was their desire to encourage, but who were not in a position successfully to compete with the class of people in the south.

The CHAIRMAN thought there could be no objection to such a resolution as this being submitted to the Council, and it would be for them to determine whether they could appropriate any fund to the purpose stated.

The resolution was then adopted.

WHAT MEANS CAN BE ADOPTED BY THE LOCAL BOARDS TO SECURE A LARGER NUMBER (a) OF CANDIDATES FROM THE ARTIZAN CLASS AT THE FINAL EXAMINATIONS, AND (b) OF FEMALE CANDIDATES AT THE ELEMENTARY AND FINAL EXAMINATIONS?

Mr. LAWTON said that, with the view of offering every encouragement to candidates, in addition to the special prize fund for the whole district Union, it had been found beneficial to have special prize funds for some of the Local Boards, and one Board had offered prizes to those candidates who obtained the highest number of marks, and also to the female who stood highest in domestic economy. In the latter case these prizes led to the formation of a class for special preparation in that subject, and had been attended with the best results, in the increased number of candidates, as well as in the proficiency displayed. Last year no certificates were awarded in that subject; this year 13 certificates were awarded to females. In the Manchester Institution a gentleman offered a prize of £5 for book-keeping, in connection

district, which produced a good competition. The special local prizes, he believed, acted most beneficially in stimulating candidates to come forward. In reference to female candidates, for two consecutive years there was a small number only in the needlework class, but in offer of a prize of £5 for shirtmaking produced an excellent competition. They did not, however, allow candidates to go in for these special prizes until they had passed the Elementary Examinations. Unless that was so, it might happen that a young woman would be able to cut-out and make a shirt, but unable to read or write. In this way the number of candidates in the Elementary Examinations was augmented. By bringing the prize into the district, and offering them through the Local Boards, he felt persuaded they would have a large increase of candidates for the more important prizes of the Society of Arts. He, therefore, said it was desirable that Local Boards should establish as far as possible a system of special local prizes.

Mr. G. C. SHERRARD (Birkbeck Literary and Scientific Institution, London) said in his Institution prizes were offered for certain subjects from a fund, subscribed by its members, to the amount of £20 or £25, which acted as a stimulus to candidates to go up on those subjects and was found, after they had studied for the local examinations, they were in a better state to go up to the examinations of the Metropolitan Association and the Society of Arts. In the present year's examinations between 30 and 60 certificates of the Society had been gained by candidates from the Institution he represented.

No resolution being proposed, the meeting passed to the consideration of the next subject, viz.,—

WHETHER IT WOULD BE EXPEDIENT TO ADOPT, AS FAR AS POSSIBLE, ONE SPECIFIED TEXT-BOOK FOR EACH OF THE SUBJECTS IN THE FINAL EXAMINATIONS?

A brief conversation took place on this subject, an opinion being expressed by many who took part in it that any restriction with regard to text-books was undesirable, and that the means by which the required knowledge was obtained should be left, as much as possible, to the choice of the candidates. The high price of some of the text-books in the examination programme was alluded to, but it was pointed out that there really was, at present, no good and cheap text-books published on some of the subjects.

WHETHER IT WOULD BE EXPEDIENT THAT THE SOCIETY OF ARTS SHOULD DECLINE TO RECOGNISE AN ELEMENTARY CERTIFICATE OF ANY GIVEN YEAR AS A PART OF THE FINAL EXAMINATIONS OF THE SAME YEAR.

In conjunction with this subject, No. 10 was considered, viz.:—

WHETHER, IN ORDER TO SECURE UNIFORMITY IN THE PREVIOUS EXAMINATIONS, THE SOCIETY OF ARTS SHOULD FURNISH AN ELEMENTARY PAPER (DIFFERENT FROM THE ORDINARY ELEMENTARY EXAMINATION) TO MEET THE CASE OF THOSE CANDIDATES WHO HAD NOT, IN ANY PREVIOUS YEAR, HAVE OBTAINED ELEMENTARY CERTIFICATES?

Mr. LAWTON remarked that it was found that the holding of Elementary Examinations some five or six weeks before the Final Examinations caused confusion, from the two examinations coming so close together. In his Union, however, they did not publish the results till the Final Examinations were over, and they took the elementary certificate for 1866 as the pass for 1867, while that for the present year would be the pass for 1868. He thought it would be very desirable to hold the Elementary Examinations at a later period of the year. If they were held at the end of March there would be more time to rally their forces, and the result would be a larger number of candidates. He would suggest that the Society should arrange for the Elementary Examinations in future being held towards the end of March.

Mr. HELLER (Lambeth Institution) thought nothing would be gained by the proposed change. The local authorities held the Elementary Examinations, and the Society allowed holders of elementary certificates to pass to the Final Examinations. Now, why should they be asked not to recognize the certificates of the same year? He saw no advantage to be derived from Mr. Lawton's proposition.

Mr. LAWTON said the Elementary Examinations were becoming a very onerous matter. In his own Union they had as many as 1,200 candidates for Elementary Examination, and he thought that justified them in treating those examinations as a distinct affair. Probably in another year they might have 2,000 offering themselves for these examinations. He wished to see the Elementary Examinations kept distinct from the Society's examinations, and if they could be held at the end of March that could be accomplished.

Mr. MARCUS considered that inconvenience would arise from the Elementary and Final Examinations following so closely upon each other. He was in favour of the existing arrangements remaining undisturbed.

The CHAIRMAN said Mr. Lawton would probably be satisfied with the discussion which had taken place on these subjects. The Secretary would report it to the Council, who would no doubt consider the expediency of making any change.

WHETHER IT IS DESIRABLE, IN THE ELEMENTARY EXAMINATIONS, TO HAVE ONE SET OF PAPERS INSTEAD OF TWO, AS AT PRESENT, BUT WITH TWO GRADES OF CERTIFICATES, ACCORDING TO THE MERIT OF THE CANDIDATES?

Lord LYTTELTON said this subject had been placed on the list by the Committee of the South Staffordshire Union, and he had been requested by Mr. Talbot, the secretary of the Union, to introduce it. The point was this—That in the Elementary Examinations there were two divisions for candidates, viz., the higher and lower grade, and for these two distinct sets of papers were provided. Mr. Talbot had given him a list of the results of the Examinations in the South Staffordshire Union in the present year, and it was curious to observe that the last twenty of the successful candidates in the higher grade and the first twenty of the lower grade might almost change places. The average age of the lower grade candidates was somewhat greater than the age of those in the higher grade, and the number of marks they obtained was higher in the lower grade than in the higher, and he was sure the two sets of candidates might have changed places. Quoting from a communication he had received from Mr. Talbot, that gentleman said:—"Another point worthy of notice is that now teachers have to instruct the scholars of the same class in two sections for the two different sets of papers. This is not so much felt where the schools are small, or where there is an ample staff of teachers, but it is felt where the staff is weak, or the school large; and where teachers grow anxious to place their scholars well in the examinations, this extra strain ought to be avoided. Then, practically, there is no real need for two sets of questions. A reference to our own list will show stronger special points in many of the lower grade candidates than in many of those of the higher grade. Considering that the scheme is fairly comprehensive, taking in Holy Scripture, English history, geography, grammar, and arithmetic, and, that all candidates may take all these subjects, there is ample scope for an examiner to classify the candidates according to merit, and to give them certificates accordingly. The only difficulty that will occur will be one for ourselves to meet; it relates to the prizes. We must make some other arrangement about them. But with that difficulty the Society of Arts will have nothing to do. I think the above are good grounds for asking the Society of Arts to do away with two sets of questions, and to let us have one set instead, but to let us have that one set so

framed as to comprehend a larger proportion of scholars than is comprehended in either of the present sets. I mean that there must be a greater variety in the proposed one set of questions than in either of the two now used." He (Lord Lyttelton) suggested that there should be only one set of papers instead of two. He had so much confidence in the judgment of Mr. Talbot on this matter that he had no hesitation in submitting this suggestion to the meeting.

Mr. J. N. LANGLEY (South Staffordshire Association) remarked that there was no difference of ages with respect to the two grades. The decision was left to the candidate whether he should go into the higher or lower; consequently, a great number went for the lower who ought to go in for the higher grade. What the Association he represented proposed was, that the same papers and the same subjects should be given to both grades. For the harder questions a higher number of marks should be given than for the easier ones, and thus the examiner would have no difficulty in awarding certificates, which might be of two or three grades, as in the Oxford and Cambridge Local Examinations, each grade being decided by the number of marks. He thought this plan would tend to improve the efficiency of the examinations, and help the masters of the schools in preparing their classes for examination.

Rev. JOHN OAKLEY thought, if they were going to start *de novo*, this might perhaps be the best plan, but he doubted the policy of making a change now.

Mr. CHESTER thought it undesirable to be constantly changing their plans.

Mr. SALES was of opinion that it was exceedingly inexpedient to alter the present system of Elementary Examinations. Many Institutions insisted upon all candidates taking the lower grade examination this year. They considered it was suited to them, as leading them gradually up from the day schools to the Final Examinations of the Society. They gave no prizes to the lower grade candidates, therefore the question of prizes did not arise. Then, having gone through the lower grade examination, they were passed to the higher grade next year, and consequently they had the benefit of two years' instruction. It was desirable to connect them for two years with the Institutions rather than allow them to pass through at once. Therefore, he said, seeing that the present scheme appeared to work well, unless some good reason could be assigned for changing it, which he thought had not yet been assigned, he thought it highly inexpedient to make the proposed change.

Mr. BENJAMIN SHAW, as Chairman of the Metropolitan Association for the Education of Adults, conceived this proposition would affect that Institution materially. It appeared to him it was striving after a perfect system with a loss of practical utility. Those who were acquainted with the labouring classes of society knew that the mere mention of their going up for examination often created the greatest fear in their minds, and if they had but one set of papers containing a certain number of questions of an advanced order, as well as the easy ones, the lower class of candidates would look at those difficult questions and be terrified, and thus the object the Society had in view, of attracting such persons to be examined, would be defeated. They should have the simplest possible elementary examinations for the lower grade, so as to get the pupils familiar with examinations. The only means by which they could hope for success in this direction was by gentle steps to lead them on to the more advanced system, which would be for their benefit. He therefore hoped they would not surround the examinations with fresh terrors. He believed that his friend Mr. Chester (who had then left the room) agreed with him as to the inexpediency of the change proposed.

Mr. MARCUS was sorry to differ from Mr. Talbot. He thought there was an advantage in the gradation of the papers, and the present system tended to keep the students connected with the Institutions for a longer time than they probably would be, under the alteration

that was now proposed. It was not a good thing that they should pass hurriedly into the Final Examinations.

Mr. LARKINS said that if they made the Elementary Examinations more difficult than they were at present, it would reduce the number of candidates, both in those and the Final Examinations. He knew seven or eight Institutions where the greatest difficulty was experienced in getting people to go up for the simplest Elementary Examinations. He was decidedly against the proposed change.

Mr. LAWTON remarked that for the last three years they had done their best in his Union to make the public acquainted with the Society's scheme of Elementary Examinations, and the members of Institutions and Local Boards were now beginning to understand it. That scheme had worked well, and he should be sorry to see any change made in it.

Mr. HELLER also spoke against the proposed alteration of system.

Mr. F. TALBOT said this subject had been placed on the list at his suggestion, but he saw the feeling of the Conference was against the proposition. He was not surprised at that, because they naturally disliked change. He had taken some interest in the working of this scheme, having been present at its birth, and had seen a great deal of its practical working. He had found great difficulty in the schools of South Staffordshire, particularly where they were under the charge of one teacher only. That teacher wished to send up scholars in the two grades, and he found it difficult to do so. It might be that the first class consisted of not more than a dozen boys, and he was obliged to divide that class in order to give instruction in the two sets of questions. This appeared to him to be a great waste of time, and it was important, especially in night schools, to economize time as much as possible; and it occurred to him that the whole difficulty might be met by having only one set of papers for both grades, instead of two as at present. He had observed some of the questions in the lower grade papers were quite as difficult as those in the higher grade. He did not see that any practical difficulty would arise out of this proposition, and though the feeling of the meeting was so much against it that, with the sanction of Lord Lyttelton, he would withdraw it, yet he thought the time would come when they would see that the practical difficulties to the teachers in night schools would be very great, and they must eventually come to some such change as he had proposed.

WHETHER ANY STEPS CAN BE TAKEN BY THE SOCIETY OF ARTS, IN ORDER TO PREVAIL UPON THE SCIENCE AND ART DEPARTMENT TO GRANT HONORARY TEACHERS' CERTIFICATES TO THOSE GENTLEMEN WHO SHALL BE RECOMMENDED BY ANY PUBLIC EDUCATIONAL BOARD?

Dr. WATTS remarked that his object in putting this subject on the paper was to ask the Science and Art Department to accept teachers of science classes who had not passed their examinations, and also to grant certificates to known competent men, who had not sat at the examinations of the Department. Some alterations had lately been made. The science payment was on results, and, if the Government paid on results alone, what did it matter whether the teaching was given by a man who held a certificate or by one who did not? The teaching was done, and should be paid for. As he had said, there had been some alteration, which he believed allowed persons who did not hold a science certificate to get payment on results; but at the same time there was value in the certificates, and, therefore, he thought it advisable that men of known scientific reputation should have granted to them the certificate of the Science Department without passing its examinations. In the Union with which he was connected they had found a difficulty in this matter. There were gentlemen who had for years successfully conducted science classes, who would not submit to go up to London to pass these examinations.

He thought some alteration in this respect was called for.

THE CHAIRMAN believed the certificate of Order of Cambridge, or that of the Government School of Mines was accepted by the Department. He presumed Dr. Watts would not go to the length of saying the same should have no certificate at all?

Dr. WATTS would even press that point. He thought if the new system were that of payment on results, results should be sufficient, whoever the teachers might be, or however the results were produced. Still, it was an advantage in holding the certificate of the Science and Art Department.

Lord LYTTLTON said it struck him as unusual in a body having examinations of its own should grant certificates upon the examinations of other bodies.

Mr. LAWTON remarked that the difficulty of the plan was increased, inasmuch as the November Examinations of the Department had been done away with, and was desirous of obtaining a teacher's certificate before the May Examinations. Consequently, those who did not afford to go up to these examinations, and who did not hold a university degree, could not act as science teachers. In his own Union there were about 40 science schools, in one of which there were 20 pupils in one class; but the Department did not raise their teachers.

Lord LYTTLTON thought it desirable that the public educational boards, upon whose recommendation a certificate of the Department should be granted, should be to be defined.

Mr. LAWTON said such as the Society of Arts, the Lancashire and Cheshire, or the Yorkshire Unions, could be competent bodies from which the recommendation could proceed.

Mr. REYNOLDS apprehended that certificates would be of little value when granted without actual examination and on recommendation only.

Mr. ISLIP (Government Inspector of Science Schools) thought the Department had been a little hardy in what was in the remarks that had been made on this subject. It was more liberal than Mr. Lawton and others gave credit for. He believed any person holding a diploma or any other public testimonial of ability in science, who received payment upon the results of his teaching in the Department, he was convinced, would deal liberally with parties producing such proofs to them.

Mr. SALES remarked that it would be more accurate if the Department would say that on the result of the examinations payment should be made, whether the proficiency had been acquired by personal study or by contact with a teacher, without insisting the latter with the requirement that he should be the holder of a certificate. They were aware that to sit at the examinations of the Science and Art Department was not the sole test of a man's fitness to be a teacher in those branches, and he might come out of the examination lower than others in a subject which was nevertheless perfectly competent to teach. There were in want of more science teachers, and no doubt they would be provided but for the restrictions in respect to the certificates which now existed.

THE CHAIRMAN thought perhaps there might be sufficient reasons for insisting upon the certificates. The object might be to get a number of persons to prepare themselves by a long course of study for the conduct of these classes. The certificate granted to them was not only proof that they had prepared themselves, but it became of money value. He thought it was important to maintain the certificates for the purpose of inducing a great number of persons to train themselves for the position of masters of Science and Art Schools. It had fallen to him to have to consider this question to some extent; he had considered the educational question, and on that his opinion was decidedly in favour of certificates.

After a further conversation the subject was withdrawn.

Upon the last subject on the paper, viz.:—

HOW CAN THE INSTITUTIONS OR DISTRICT UNIONS ASSIST THE MOVEMENT NOW BEING MADE BY THE SOCIETY OF ARTS TO SEND SELECTED WORKMEN TO EXAMINE AND REPORT UPON THE PARIS EXHIBITION?

Observations were offered.

Dr. WATTS then proposed a cordial vote of thanks to Mr. Bruce for his kindness in attending the Conference, and for the able and courteous manner in which he had presided over the proceedings.

This was seconded by Lord LYTTLTON, and carried by acclamation.

ANNUAL GENERAL MEETING.

The Annual General Meeting, for receiving the Report from the Council, and the Treasurers' statement of Receipts, Payments, and Expenditure during the past year, and also for the Election of Officers, was held, in accordance with the Bye-laws, on Wednesday, the 26th inst., at four p.m., WILLIAM HAWES, Esq., Vice-President of the Society, in the chair.

The CHAIRMAN, before entering upon the business of the meeting, desired to express the sincere regret he felt, and that felt by every member of the Council—and he might say by every member present—that it became his duty to preside over the meeting this day. During the long period he had enjoyed the friendship of Sir Thomas Phillips, he had fully appreciated his generous and kindly character; and his death left a blank in the Council of the Society which it would be difficult adequately to supply.

The Secretary having read the notice convening the meeting, the minutes of the last Annual General Meeting, and of the subsequent Special General Meeting, were read and signed.

The Chairman then nominated the Rev. James Spong and Mr. O'Hagan as scrutineers, and declared the ballot open.

The Secretary then read the following

ANNUAL REPORT OF THE COUNCIL.

In compliance with the Bye-laws, the Council now lay before the Society a statement of their proceedings during the past year. Before, however, they enter upon the general business of the Society, they desire to express their deep concern for the loss which the Council and the Society have sustained in the death of their Chairman, Sir Thomas Phillips. The long period during which he presided over their deliberations, elected by the unanimous voice of his colleagues, is in itself unmistakable testimony of the estimation in which he was held by them. His business-like habits, his honest zeal and earnest exertions on behalf of the Society, his thorough appreciation of its objects and interests, combined with rare integrity of mind and genial good temper, rendered him especially qualified for the office he held, and the Society will not readily supply his loss.

ART-WORKMANSHIP PRIZES.

The Council have much satisfaction in recording a considerable advance in the response made this year by competitors for these prizes, the numbers being 109, as against 61 of the previous year. The advance, moreover, is not merely in numbers—the quality of the works sent in surpasses that of any previous year, and the judges, Messrs. R. Redgrave, R.A., and Mr. Digby Wyatt, in their report bear pleasing testimony to this fact, and express their gratification in recognising that the encouragement given by the Society “to the improvement of Art-Workmen in so many departments of skilled industry is at length bearing fruit.” In the competition this year, liberty was given to artisans to exhibit works after other designs than those prescribed in the classes enumerated in the first section of the programme. Many have availed themselves of this relaxation of the conditions, and very highly creditable work has been sent in. The judges, in speaking of this department, after giving high praise to many of the works, “congratulate the Society upon the institution of this section, and upon the results of its action in this respect.” The amount of prizes awarded this year has been £182 8s. 8d. as against £174 last year. In carrying on this work the Society has been again assisted by the Worshipful Company of Salters, who contribute annually £10 to the Prize Fund, and this year the Worshipful Company of Clothworkers also contribute £10, and the Worshipful Company of Goldsmiths have signified their intention to aid the Society by offering prizes of £10 and £5 for the encouragement of workers in the precious metals. A selection of the prize works of the competitors is now being exhibited by the Society at the Paris Universal Exhibition. The Council have decided to continue their offer of prizes in this department, and, under the advice of a Committee, have issued a revised list for the current year.

MEDALS.

The Albert Medal has this year been awarded to Mr. W. Fothergill Cooke and Professor Charles Wheatstone, F.R.S., in recognition of their joint labours in establishing the first Electric Telegraph.

It will be remembered that the first Albert Medal was awarded, in 1864, to Sir Rowland Hill, K.C.B., “for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which, have, however, not been confined to this country, but have extended over the civilised world.” The second medal was awarded, in 1865, to His Imperial Majesty the Emperor of the French, “for distinguished merit in promoting, in many ways, by his personal exertions, the

international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects." The third medal was awarded, in 1866, to Professor Faraday, D.C.L., F.R.S., for "discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

The Council think it right to remind the members of these several awards, in order to keep in their recollection the very high standard of merit which they are intended to mark.

In making the award this year, the Council were placed in a somewhat peculiar position, inasmuch as by the terms upon which the medal was established they could only make one award, whilst the great object accomplished was due to the combined labours of two men. They felt, however, that so great a national work as the Electric Telegraph was especially worthy of reward by this Society, and that the Albert Medal could not be more worthily bestowed than in recognition of the services of those to whom the introduction of the Telegraph was due. The award having been made, they have directed that the medal be struck in duplicate, and a copy, with a suitable inscription, be presented to each of the above-named gentlemen. The Council feel assured that in selecting the introduction of telegraphy for the award of the Albert Medal, they will have the unanimous concurrence of the members of the Society.

The Council have awarded the Society's Silver Medal to James Fergusson, Esq., for his paper "On the Study of Indian Architecture;" to Clements R. Markham, Esq., for his paper "On the Tinnevely Pearl Fisheries;" and to S. J. Mackie, Esq., for his paper "On the Construction of Iron Ships, and their Preservation from Corrosion and Fouling by means of Zinc Sheathing." All these papers were read at evening meetings of the Society.

HARVESTING CORN IN WET WEATHER.

The effect of the last year's wet season upon the harvest drew the attention of the Council to the importance of something being done, if possible, to obviate or mitigate the injury which the public suffer from this cause. After consultation with, and under the advice of, a committee of gentlemen skilled in agricultural pursuits, the Council determined to offer the Gold Medal of the Society, and a Prize of Fifty Guineas, for the best Essay on the Harvesting of Corn in Wet Seasons.

The first part of such essay—after noticing the various systems at present adopted in damp climates for counteracting the effects of moisture upon cut corn in the field, and for avoiding such

exposure in wet seasons by peculiar harvesting processes—should furnish a practical and analytical exposition of the best available means.

1st. Whereby cut corn may be protected from rain in the field.

2nd. Whereby standing corn may, in wet seasons, be cut and carried, for drying by artificial process.

3rd. Whereby corn so harvested may be dried by means of ventilation, hot air, or other means, with suggestions for the storage both in the stack and after thrashing.

4th. Whereby corn, sprouted, or otherwise injured by wet, may be best treated for grain, or feeding purposes.

The whole to be supplemented by a statement of practical results, and the actual cost of an system described; and by authenticated estimates of any process proposed for adoption, based on existing, but uncompleted experiments.

These requisitions are given suggestively, and are not intended to bind the writer to the order or to limit the treatment of the subject, provided it be kept within the scope of practical experience and utility.

The essays are to be sent in to the Secretary on or before the 1st of January, 1868.

The Council reserve the power to withhold the whole or part of the prize, in the event of no essay being, in the opinion of the judges, of sufficient merit.

FOOD COMMITTEE.

Early in the Session the Council resolved that a Committee be appointed to inquire and report respecting the food of the people, especially, but not exclusively, the working classes of the people; and that, having regard to the publications of the Privy Council and other documents, which illustrate the defective amount of nutritious food available for the population at large, the said Committee do report respecting the resources which are, or might be rendered, available for the production, importation, and preservation of substances suitable for food, and for improving the methods of cooking in use among the working classes." This Committee, under the chairmanship of the Right Hon. H. A. Bruce, M.P. has held many meetings, very fully attended, and has diligently prosecuted its inquiries; the evidence which has been given before it has been published from time to time in the *Journal*. The Committee, in their first report to the Council state:—

By the terms of their appointment, they were "to inquire and report respecting the food of the people, especially, but not exclusively, the working classes of the people," and they were instructed "to report respecting the resources which are or might be rendered available for the production, importation, and preservation of substances suitable for food, and for improving the methods of cooking in use among the working classes." The Committee feel that much of their task remains uncompleted owing to the shortness of the time during which

they have been at work as compared with the extent of the inquiry, and they therefore beg strongly to recommend that they should be allowed to continue their labours, and should not be considered as making in any sense a final report.

After careful consideration of the points to which their investigation should be directed, they appointed four Sub-Committees; one on meat, one on milk, one on fish, and one on the subject of the cooking and cooking utensils in use among the working classes with a view to their improvement.

On the first of these subjects much evidence of various kinds has been taken, and much information received, both from scientific and practical men, but as the substance of this has appeared from time to time in the *Journal*, it is not deemed necessary to recapitulate it here.

The Committee divided this branch of their inquiry into

(1) The transport of live stock and of meat in a fresh condition.

(2) The methods of preserving meat, with a view to its importation from a distance.

On the former head, they are not at present prepared to make any distinct suggestions, but they are not without hope that they may be able to do so hereafter if their inquiries are continued.

Under the latter head, they have examined various plans, but the only one by which they have as yet found that unsalted meat in a solid eatable condition has been largely imported, is that followed by The Australian Meat Company. The process is that long used for preserved provisions. The beef arrives in tins from which the air has been excluded, and, from the heat employed, is sufficiently cooked to be eaten without further dressing. It may, however, be stewed and served hot, if preferred, and is fairly palatable. The Committee would suggest that to render it more valuable, the proportion of fat should be diminished, and the temperature of preparation kept down to the lowest limit compatible with perfect preservation. It is at present supplied to the public at the rate of 7d. per pound, retail price.

The extract of meat manufactured according to Liebig's process may be fitted for use in special circumstances, but does not seem suited to form a substantive article of food.

The Committee would add, however, that a specimen of dried and powdered beef from Queensland has been laid before them, prepared by Mr. Alexander, of Brisbane, in that colony; and they are taking means to obtain a larger supply for the purpose of a more complete examination. The sample, though sent over from Queensland in a common canvas bag, and thus fully exposed to variations of temperature and the action of the atmosphere, was perfectly sweet and fresh; while the analysis by Dr. Voelcker and Professor Taylor showed that it possessed, in all material points, weight for weight, four times the nutritive properties of ordinary butcher's meat. Unfortunately, no evidence is at present attainable as to the price at which it could be sent to this country, a point which would, of course, materially affect its value as an article of general consumption.

Professor Gamgee, also, has drawn attention to a peculiar method of killing animals, by which he maintains that their flesh may be preserved much longer than if slaughtered in the ordinary way. The Committee have gone into the subject with much care, and have witnessed some experiments; but they are not at present able to express any opinion on its merits. They think that further and more lengthened trials would be desirable.

The same remarks apply to Mr. Sloper's process for preserving meat by enclosing it in tins filled with a gas of particular properties. One successful example has come before them, but they cannot speak decidedly, without further experiments.

Coming to the subject of milk, the attention of the Committee has been much directed to the supply of country milk to London, which has very largely increased during the last two years, and is likely to do so still more. The chief difficulty arises from the imperfect means of conveyance, which are open to much improvement, and the Committee recommend the adoption of the French system in the construction of the milk cans, with corresponding alterations in the railway vans. The French cans are much smaller, and more easily moved about, and as they are quite filled with milk, and the opening is carefully closed with a close-fitting stopper, the milk is less shaken than in the large imperfectly-filled cans used in this country. It would be well if railway companies could be induced to insist on the use of such cans, at all events when a new district of country begins to take part in supplying milk to the metropolis.

Could milk be supplied in larger quantities and at a cheaper rate from the country to our large towns, a valuable means of nourishment would be open to all, especially to the young, who often suffer seriously in health from the want of it.

On the subject of fish the Committee have an important recommendation to make to the Council, on which they lay much stress. Their inquiries have of late been limited to a few points only, but evidence brought before them shows that fish forms a most important article of food, much sought after by all classes. The demand for it is sufficient to absorb any increased supply that can be obtained, and the means of distribution, although capable of great improvement, are, even at the present time, such as will place the commoner kinds of fish within the reach of the working classes at a very reasonable price. It further appears probable that the fisheries of this country might be developed very considerably if a greater amount of capital, skill, and energy were devoted to them.

Hence the Committee suggest that, to attract public attention to this subject, the same means should be used which have been employed in Austria, France, Sweden, Norway, Denmark, and Holland, and that an International Fishery Exhibition, similar to those which have been held in the countries just mentioned, should be set on foot in England. The fact that the one now taking place at the Hague is the second which has been held there, seems conclusively to show that the results have been found to be beneficial.

The unrivalled capabilities of this seagirt country, and the importance of increasing its supply of nutritious food, seem alike to indicate that England is deeply interested in following such examples; if, indeed, she should not have taken the lead of other nations.

It would appear that the utility of such exhibitions suggested itself to the Commissions on the Sea Fisheries of the United Kingdom, though they rather contemplated the promotion of them by the efforts of a special society. They say, in their Report:—"When we consider the amount of care that has been bestowed on the improvement of agriculture, the national societies which are established for promoting it, and the scientific knowledge and engineering skill which have been enlisted in its aids, it seems strange that the sea fisheries have hitherto attracted so little of the public attention. There are few means of enterprise that present better chances of profit than our sea fisheries; and no object of greater utility could be named than the development of enterprise, skill, and mechanical ingenuities which might be elicited by the periodical exhibitions and publications of an influential society specially devoted to the British fisheries."

The Committee intentionally abstain from going into any details, being persuaded that the labours and experience of the Council, in connection with the great international exhibitions, render it the fittest body in the country to originate such a design, and to suggest the proper steps for its successful execution.

In relation to the subject of cooking, there is at present but little to report. The Sub-Committee have had several meetings, but as they found that an officer of the Royal Engineers was directing his special attention to the various kinds of improved fire-places and cooking utensils exhibited at the Paris Exhibition, it was thought best not to proceed with the subject (of which they fully recognise the importance), until they were in possession of the information which will no doubt be derived from any report that he may make.

The attention of the Committee has been so taken up by these four subjects, that they have been unable to make any inquiries upon other points equally important, viz., cereals and other vegetable food generally; fermented and unfermented beverages; combinations for the preparation of food; and the very momentous one of adulterations and other frauds in the sale of food. Through the kindness of Lord Stanley, they have received documents relating to the laws of foreign countries on the last-named question, upon which further legislation appears to be needed in this country.

They desire also to call the attention of the Council to the bearing of the investigations of M. Mège Mouriés on the bread-food supply of the people. The results of his investigations into the preparation of wheat flour, and the processes of panification, have already been given in detail in a recent number of the *Journal* (May 10, p. 394). An improvement upon existing practices, based on sound philosophical principles, which adds not only to the quantity, but also to the nutritive quality of the available produce of such an important article of daily food as wheat flour, appears to the Committee to be worthy of public recognition by the Society of Arts, and of being carried out into practical existence. The separation of the *true bran* from the grain does not appear to present much mechanical difficulty; while any prejudice that might at first exist against the colour of bread from flour thus prepared would gradually disappear as its superior quality and economy became known.*

The Council does not doubt that the great importance of the subject of the food of the people will be recognised by the new Council now to be appointed, and that they will renew the appointment of the Food Committee. With regard to the recommendation that an Exhibition of Fishery Appliances should be held in this country, the Council have requested a Special Committee to consider and report what steps can be taken to practically carry it into effect.

CANTOR LECTURES.

Two courses of these lectures have been given during the Session, one by Mr. Chaffers, on Pottery, and one by Mr. Hullah, on Music. In both cases, as the courses proceeded, it became necessary to extend the number of lectures beyond that originally contemplated. Full abstracts of these lectures have appeared in the Society's *Journal*. The information on subjects connected with the objects of the Society, thus imparted to the public by men eminent in their several specialities, and the interest which the members take in them, fully justify the Council in the establishment and in the continuance of these lectures, which may

be considered now as a settled part of the Society's operations.

FINE ART COPYRIGHT.

The Council have again this year endeavoured to procure an amendment of the laws relating to Copyright in Fine Art. With this object in view they have had a Bill carefully prepared for consolidating and amending the law, which at present is in a very unsatisfactory condition, and wholly inadequate to repress the piracy which seem daily extending, to the injury alike of artists, purchasers, and publishers. The Council sought the aid of the Government to bring in and prosecute their Bill in Parliament. The state of political matters in the House of Commons caused considerable delay in obtaining the decision of the Government; and has rendered it necessary to postpone any further attempts at legislation till the next Session of Parliament. The following is the reply to the Society's application:—

Office of Committee of Privy Council for Trade
Whitehall, 28th May, 1867.

SIR,—Lord Derby having referred to this department a draft bill, which has been prepared by direction of the Council of the Society of Arts, for consolidating and amending the law of copyright in works of fine art, I am directed by the Lords of the Committee of Privy Council for Trade to state to you, for the information of that body, that after a careful consideration of the proposed bill, they do not think that its provisions are on the whole such as would tend to produce a satisfactory measure of legislation.

My Lords are of opinion that, in dealing with this question, it would be desirable that any proposal which might be submitted for the consideration of Parliament should not be limited in its operation to works of the art only, but that, having in view the existing state of the laws with regard to copyright generally, it would be expedient that such a measure should embrace the entire subsisting copyright laws of the United Kingdom.

The question of the amendment of these laws has for some time occupied the attention of Her Majesty's Government; but my Lords are not prepared, under the present circumstances, and considering the advanced period of the session, to undertake to deal with the subject this year.

It also appears to my Lords that it would probably be necessary to institute further investigations, with a view to ascertain the special points upon which legislation is most requisite, and it will therefore be a matter for consideration whether this object could not perhaps be best attained by the appointment, in the early part of the ensuing session, of a select committee of either House of Parliament, to consider the whole question of the consolidation and amendment of the laws of copyright.

I am, Sir,

Your obedient servant,
HENRY G. W. MANLY.

F. Le Neve Foster, Esq., M.A.,
Society of Arts, John-street, Adelphi.

MEMORIALS OF EMINENT MEN.

The Committee in charge of this subject have had tablets prepared for the purpose of marking the spots where eminent men have lived and died (as referred to in last year's report), and the work has been commenced by placing a commemorative tablet on the house where Byron was born, in Holles-street, Cavendish-square.

* The Council have since learnt that M. Mège Mouriés' process has been for several years past, and is at the present time, in actual operation on a large scale at the "Usine Municipale de Seclion," at Paris. About 25,000 kilograms of bread, equal to 13,000 to 14,000 wafers, are made daily at this establishment. The quality excellent, and its nutritive properties practically proved.

Tablets are about to be affixed as follows, leave having been obtained from the respective owners, viz.—3a, King-street, St. James's, occupied by H.I.M. the Emperor of the French when in this country; 141, New Bond-street, on the house in which Nelson resided previous to his departure for Trafalgar; 47, Leicester-square, the residence of Sir Joshua Reynolds; 7, Craven-street, Strand, where Franklin lived; and 36, Castle-street, Oxford-street, where James Barry had his abode.

ARTIZANS' VISITS TO PARIS.

The following minute, which has been passed by the Council, fully explains their action in reference to this object:—

At the last and former International Exhibitions held in this country, arrangements were made by the French Government, to facilitate the visits of skilled artizans, and interesting reports on the exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council of the Society of Arts have resolved to raise a fund, to be employed in aiding a limited number of English workmen to proceed to Paris for the purpose of studying the present French Exhibition.

To carry this object into effect, they have agreed on the following plan:—

1st. That a number of selected workmen (the number to depend on the amount of funds at the disposal of the Council) shall be assisted to proceed to and remain in Paris a sufficient time (say three weeks), for the purpose of making a careful study of the exhibition, and of such factories and workshops as they may desire to visit.

2nd. That every man so assisted shall, on his return, make a report to the Society of what he has observed during his stay, in reference to the special industry in which he is engaged, and that it be made a condition of his grant to each man that one-third of the amount be retained until his report shall be supplied to the Society.

3rd. The Council think it will be undesirable to fix the exact time for, or to prescribe the duration of, these visits, or to interfere with any of the arrangements the men may desire to make for their own accommodation; but, in order that they may take advantage of the facilities provided by the Commission organised by the French Government for the study of the exhibition, the men will be placed in communication with that Commission on their arrival in Paris.

4th. A considerable sum will be required satisfactorily to accomplish the important object undertaken by the Society, and, in order to raise these funds, the Council have determined to appeal to the members of the Society, who must be interested in the successful results of this movement, in the belief that they will not hesitate to join a subscription for the furtherance of the undertaking; and they propose at the same time to communicate with the various Chambers of Commerce, inviting their counsel and support. The Council have decided to commence a subscription by a vote of one hundred guineas from the funds of the Society.

The Council trust that the members will aid them in this matter and enable them to carry it on a sufficiently extended scale the important object they have in view. They have the pleasure of stating that H.R.H. the Prince of Wales, as the President of the Society, has given his hearty sympathy with the undertaking by subscribing thirty guineas to the fund,

and many members have already signified their intention to join in the subscription. The list has already appeared in the *Journal*. It is proposed that these visits shall commence after the 1st of July, when the awards of the juries will have been publicly announced. An officer (Col. Ewart, R.E.) has been specially appointed by Her Majesty's Commissioners, whose duty it will be to give all necessary aid to the workmen on their arrival in Paris.

MUSICAL EDUCATION.

The Committee in charge of this subject have made two reports to the Council, which have been published at length in the *Journal*. In these reports the Committee point out that a National Academy should afford gratuitous education to a limited number of persons having great musical gifts, who, after proper training at the public expense, would engage to devote their talents to the service of the public as professors of the art of music, and that the form in which Parliamentary assistance could be best afforded would be by scholarships, which should be held by candidates who, in open competition, had proved that they are endowed with the gift of musical ability.

The Committee also express an opinion that besides the training of free scholars, the Academy should be open to the public at large on the payment of adequate fees; and, as soon as the institution shall have obtained public confidence, the cathedrals and various other corporations will (it is hoped) provide the means of sending to the Academy young persons of musical genius; and the Committee recommend that the Society of Arts should itself set the example of such endowments by establishing a limited number of scholarships.

The Committee consider that, before Parliament can be asked to increase its present vote to the Royal Academy of Music, the Academy should provide, through the voluntary aid of the public, permanent and suitable premises, possessing all requisite facilities for practice and study; but probably three years must elapse before they can be built even after the funds are obtained. In the meantime, the Committee consider that every effort should be made by the Academy to enlarge its basis of action, and to establish an effective system of responsible administration. When the public are satisfied with the promise of an efficient Academy, it may be expected that they will contribute towards the erection of suitable premises.

The Committee draw attention to the fact that the Royal Academies of Music of Paris, Brussels, and Naples, being instances of highly successful institutions, present useful suggestions for the re-organisation of the Royal Academy of Music. In these Academies a considerable number of students are educated gratuitously,

and the Committee consider that at present about two hundred students might be fixed as a proper number to receive gratuitous training at the Royal Academy, and that of this number one hundred, selected by public competition, should be supported by public funds disbursed under ministerial responsibility, the remainder if possible by colonial, municipal, or other corporate funds, and by private endowments and subscriptions. Arrangements should then be made to allow about 100 private students in addition to enter and pay adequate fees for their instruction. As far as the Committee are enabled to judge, they consider that the cost of properly training two hundred free students would be about fifteen thousand pounds sterling a year.

The Council have had these reports under their consideration, and have expressed their willingness to establish experimentally, in connexion with the Academy, for a limited period, four Free Scholarships of £50 a-year each, for the study of vocal and instrumental music, to be called the Society of Arts Scholarships, provided that the Royal Academy be placed in a permanent and efficient position, in accordance with the reports of the Committee.

INSTITUTIONS IN UNION.

The Council congratulate the Society on the very great progress which has been made in the examinations connected with this branch of the Society's operations; and they refer to the Secretary's report, read at the Conference of Institutions on the 19th instant, for the details connected with them.

It will be seen that there has been a very large increase in the number both of the candidates examined in the Final Examinations, and of the places at which these examinations were held; that the examiners have, with very few exceptions, reported most favourably respecting the character of the papers referred to them; that there has been some increase in the number of female candidates who have obtained certificates; that a larger amount of prizes has been carried off than in any previous year; that those prizes have been obtained by candidates in all parts of the United Kingdom, viz., Aberdeen, Belfast, Bromley, Chatham, Chelmsford, Deptford, Devonport, Glasgow, Halifax, Huddersfield, Leeds, London, Manchester, Pembroke Dock, Portsmouth, Richmond, Rugby, Slough, Southampton, West Bromwich, and Wolverhampton. The Society has had the advantage of the co-operation of the Royal Horticultural Society and the Royal Geographical Society, of the proprietors of the *Gardeners' Chronicle*, and of certain City Companies, viz., the Goldsmiths and the Coach and Coach-harness Makers; and this co-operation is likely to be extended and to have an important bearing on the examinations in future years.

The Elementary Examinations, which are conducted, not by the Society of Arts itself, but by the Institutions and District Unions connected with the Society, and are important auxiliaries to the Society's system, have been conducted this year with great success, and on a very much larger scale than in previous years; and on a review of the whole subject, the Council can cordially congratulate the Society on the success of its endeavours to improve the education of the working classes, though much still remains unaccomplished, and the great object of technical instruction demands the best attention of the new Council.

FINANCE.

The balance-sheet and statement of the financial condition of the Society have been published in the *Journal*, in accordance with the Bye-laws, and show the satisfactory position of the Society's pecuniary affairs. The Society commenced its new lease at Lady-day last and the items of the balance-sheet show a larger balance at the Society's bankers, and a smaller amount of liabilities as compared with the corresponding period last year, while the sum of £200 has been added to the Society's investments. The annuity of £50 which the Council have for some years paid to Mrs. Cantor, the mother of the late Dr. Cantor, has lapsed, by the death of that lady, which took place at Copenhagen in January last.

The CHAIRMAN asked whether any member present desired to offer any observations upon the report which had just been read?

No member having responded, the Chairman then put to the meeting that the report be received and adopted, which was carried.

The CHAIRMAN said he had received a letter from a member, touching upon various matters connected with the Society, but as the letter was not signed, he thought that as a matter of principle it would not be desirable to read it, although he might observe that it contained nothing in any way objectionable, but the contrary. If, however, the writer would send in his name, he was sure the letter would have the best attention of the Council. It had, he believed, been sometimes asserted that the Cantor Lectures acted unfavourably, in lessening the attendance at the Wednesday evening meetings, and also that the lectures had not this year had such large audiences as formerly. With regard to the first assertion, his own observation and the information he had received from others led him to doubt its correctness. Possibly, with regard to some of the Cantor Lectures this year, there might be some truth in the latter statement, but certainly the information given in them was most valuable, and he thought they were generally appreciated by the members. With regard to the statement of accounts which had been laid before them, he thought it was now in as perfect and clear a form as possible, and for that they were in a great degree indebted to the auditors, especially to one of them, who in a former year had pointed out objections to the form then adopted, and had since kindly accepted the office of auditor, and given a much valuable time to the duties of that office.

Professor THWANT suggested that it would be interesting to members if short descriptions of the pictures adorning the room in which they were

d were published in the *Journal*. He might, with reference to the proposed visit of the to Paris, that the Geological Society of France probably hold a meeting there at the end of July.

ballot having remained open one hour, the scrutineers having reported, the Chair declared that the following members had been elected to fill the several offices. The names of the members who have not, in the past year, filled the offices to which they have been elected:—

COUNCIL.

PRESIDENT.

H.R.H. the Prince of Wales, K.G.

VICE-PRESIDENTS.

Bodkin (Assistant-Secretary).	Lord Henry G. Lennox, M.P.
P. Boileau, Bart.	Lord Lyttelton.
Hon. H. A. Bruce, M.P.	<i>The Duke of Marlborough.</i>
<i>Duke of Buckingham.</i>	Right Hon. Sir John S. Pakington, Bart., M.P.
Chesler.	The Marquis of Salisbury, K.G.
de Cole, C.B.	Sir Francis Sandford.
de l'Isle and Dudley.	Thomas Twining.
Gassiot, F.R.S.	Vice-Chancellor Sir Wm. Page Wood, F.R.S.
Earl Granville, K.G., &c.	<i>The Archbishop of York.</i>
Sam Hawes.	
John Hoskyns.	

COUNCIL.

SECRETARY.

Peter Le Neve Foster, M.A.

FINANCIAL OFFICER.

Samuel Thomas Davenport.

At the conclusion of the General Meeting a special Meeting was held, when the following candidates were balloted for and duly elected members of the Society:—

Mr. John, 12, Elvaston-place, South Kensington, S.W.
 Mr. Grey, Charles, jun., 166, New Bond-street, W.
 Mr. Riker, J., 5, Birchinn-lane, E.C.
 Mr. Welfield, Arthur William, 8, Adelphi-terrace, W.C.
 Mr. James, Robert B., Nevill-park, Tunbridge Wells.
 Mr. James, John C., 12, Barnsbury-road, Islington, N.
 Mr. Edwards, Robert, 26, Lower-street, Deal.
 Mr. Ward, G. Eugene, 13, Malden-crescent, N.W.
 Mr. McMillan, John, 7, Westminster-chambers, S.W.
 Mr. Jackson, Alfred, 6, Westminster-chambers, S.W.
 Mr. Michael, W. H., Chancery-road, Holloway, N., and 4, King's Bench-walk, Temple, E.C.
 Mr. Ramsey, Ewart Simon, 6, Raymond-buildings, Gray's-inn, W.C.
 Mr. Coester, William, F.R.G.S., Linden-villa, Tottenham, N.
 Mr. Litherford, Charles, 82, Oakley-road, Southgate-road, N.
 Mr. Lykes, John, 280, Regent-street, W.

Mr. Teulon proposed a cordial vote of thanks to Mr. Lykes for his conduct in the chair, and, he might add,

for all his eminent services to the Society for several years past.

Mr. WATERHOUSE HAWKINS seconded the motion, which was carried by acclamation.

PARIS EXHIBITION.

The classes of textile fabrics are not very fully represented on the British side, but it cannot be said that they are poor; on the contrary, the opinions of intelligent and impartial foreigners appear to be decidedly favourable.

In the cotton class there are only about thirty exhibitors, but the fabrics have been greatly admired, especially what are called in the trade soft goods, that is to say, fabrics with little dress in them; broad cloth for sheeting and other purposes, in some cases more than a hundred inches wide; cotton velvets, velveteens, and fabrics of that class; and also sewing cotton, and twist for the sewing machine.

In flax goods, the United Manufacturers of Ireland and many private exhibitors make excellent shows; the catalogue contains only twenty names, but the combined national exhibition of Irish linen manufactures includes about thirty more. The damasks, linen cloth, fine fabrics, sail cloth, and other fabrics have been much admired, and the excellent manner in which most of the cases are arranged adds greatly to their value in an exhibition point of view; in many cases the raw flax, yarns, threads, and fabrics are shown together, so as to become valuable educational as well as practical collections. Another point worthy of note as regards this class is the evidence to be found on all hands of a regular import into France; there is scarcely an important manufacturer who has not his Paris agency.

In the combed wool and worsted class there are but nine entries in the catalogue, but Bradford exhibits collectively under the head of the Chamber of Commerce, and its exhibitors must be numerous; the two Bradford cases contain a very fine collection, commencing with samples of wool of all kinds, a capital series of yarns, and an immense number of fabrics, including moreens, mohair, alpaca, lastings, Balmoral crape, camlets, princettes, mixed goods, Orleans cloth, damasks, knickerbocker, winseys, and Italian cloth.

The next class, that of carded wool and woollen fabrics, is strong both in numbers and quality; there are more than a hundred exhibitors, including the Batley Chamber of Commerce, which makes a collective exhibition of perhaps twenty firms; the thick coatings, fabrics for trousers and skirtings, flannels, railway rugs, tweeds, and fancy woollen and mixed stuffs, are certainly not to be equalled in any other department of the Exhibition, and the admirable finish of goods of low and moderate price has called forth the highest encomiums. The Scotch manufacturers come in for their full share of this admiration; the tartan shawls and other fabrics of the same class are eagerly sought by French buyers, as well as by those of other parts of the Continent; and the remark that was made above with respect to the demand for Irish and other linens will apply with quite as much force to English and Scotch woollen and mixed goods of several classes.

The British silk manufacture stands in a very different position to those of cotton, linen, and woollen; in this case we almost of necessity fill a secondary position; we exhibit our products in the very capital of silks; we "carry our coals to Newcastle;" but our silk manufacturers are in no way dishonoured; they cannot cope with Lyons in decorated fabrics, but they have specialties of their own, which cannot be overlooked; the silk velvets, and especially those with cotton backs, are admirable; there are pieces of watered silk, *moirés antiques*, from Spitalfields, which surpass in excellence and beauty the productions of any looms in the world. There is an admirable show of fancy silk scarfs, equally remarkable for solidity, good design, dyeing, and moderate price;

and there are the beautiful Irish poplins, which have never yet been equalled in any country. All these articles are now in more or less demand in Paris and elsewhere on the Continent, and the names of some of the best-known houses may be found mentioned as customers in the cases of our English and Irish exhibitors. There are two other kinds of goods in this class for which England is unrivalled, namely, crape, black and coloured, and plain and figured silks produced in the power-loom; this last is a novelty which deserves special attention.

The lace class is very well filled; the products of the Honiton and other cushions, the Irish point and other hand laces, are very beautiful, and the machine lace makers of Nottingham make a remarkably fine show. The imitation Spanish, or Pusher lace shawls, as they are called in the trade, are remarkably beautiful and in great demand in France, but the machine-made curtains have perhaps attracted more attention than anything else in this class; they are equally remarkable for improvement in design as for increased size. There are examples in the Exhibition fourteen or fifteen yards in length, and some specimens of design which deserve the highest approbation. The circular avenues in the English department are hung with lace curtains, and no decoration could possibly be more fitting or more beautiful, especially in connection as they are with simple fringe and elegant pendant lamps. Such are a few of the impressions made by a careful study of the textile fabrics on the British side of the Exhibition.

Some of the more prominent awards of the jury have been published in the journals of France and England, but such lists are not official, and probably not complete or even accurate as far as they go; we think it better, therefore, to abstain from quoting them, and await the appearance of the official list.

A paragraph, relating to the awards, which appeared a day or two ago has attracted considerable attention; the purport of it is, that with the view to rendering the decisions of the jury complete and irrefragable, a committee has been formed to make an inquiry, previous to the distribution of the awards, as to the commercial respectability of those exhibitors to whom honours have been awarded; the reason for this is given as follows:—After the two universal exhibitions of Paris and London there occurred some cases "of failure and bankruptcy, which followed so closely upon the distribution of prizes as to give rise to the supposition that they must have been foreseen and dissimulated by those interested. It is not fit that public morality should be taken by surprise; it is right to reward progress, but only that which is brought about by regular means and honest labour." It appears that a committee of revision is now at work with a view to eliminate any such cases, and that the president is M. Devnick, who has had a long experience at the tribunal of commerce.

The visits of working men are now becoming important; last week M. Duqué de la Fauconnerie, president of the Agricultural Committee of Mortagne-in-the-Orme, headed a party of 300 farmers and workmen from Perche. They left Condé-sur-Huisnes by rail on Wednesday night, and reached Paris, a distance of 87 miles, at three o'clock on the following morning, rested two hours at the model lodging-house, close to the Exhibition, then started for a steam-boat trip to the other end of Paris, returning by omnibus, and arrived at the Exhibition at half-past seven. They visited the park and the reserved garden, lunched there and left at mid-day for the agricultural annex at Billancourt, where they dined at half-past six o'clock, and reached their lodgings at about nine. On the following morning they were at the Exhibition in the Champ de Mars at seven o'clock, staid till ten at night, and then returned home; the whole cost of the trip, including three francs per head for admission to the Exhibition, was 23 francs for the leaders of the expedition, and 20 francs for their workmen.

The expeditions organised by the Working Men's

Club and Institute Union of London have already brought two parties of working men to Paris, the first consisting of two hundred, and the second of more than eighty men. Another party of about three hundred is expected immediately. Mr. Layard, M.P., was in Paris with the former party, and accompanied the workmen in some of their visits. The British Commission has placed a capital room at the disposal of workmen visiting the Exhibition, where they can write letters or meet each other; and, what is more important still, obtain information on many points. For this latter purpose a gentleman speaking French and English has been appointed secretary or superintendent. The French *ouvriers* who visited London and reported on the Exhibition of 1862 have also offered their services to accompany the English visitors over the Paris workshops, a delicate attention that deserves to be remembered. These delegates were delighted with the cordial reception they met with from the workmen of London, and thus show their gratitude in the most acceptable manner. A party of about sixty Italians, and some other parties of working men, have also arrived in France within the last fortnight.

A few days since the foreign delegates of the tenth group were invited to attend a meeting at the asylum for convalescent workmen, when M. Wolowski, professor of political economy, delivered an address on the *économie* of the Exhibition.

Two grand entertainments are talked of for the latter end of July; one given by the Imperial Commission to the members of the jury, the great prize-holders, and all the notabilities of the Exhibition; the other, a banquet to be offered by the exhibitors to the Emperor himself, who, it is said, has given a conditional acceptance.

Conferences are now being held in the hall erected in the grounds of the Exhibition for that purpose, by the Abbé Moigno, M.M. Brunnet, Rumkorff, Geisler, and other *savants*, besides lectures on music and other subjects.

The attendances at the Exhibition vary greatly; but they continue to be very large; they range, at present, between 50,000 and 80,000. The arrival of the Viceroy of Egypt, and the expected coming of the Sultan, have added and will add greatly to the attractions of the Exhibition; there has, in fact, been a constant succession of distinguished guests, which shows no sign of diminution, but the contrary.

ADMISSION TO PALACES, MUSEUMS, &c. DURING THE PARIS EXHIBITION.

It has already been announced that special facilities are afforded to visitors during the entire season of the present exhibition, but every day adds some new item to the list of attractions. The palaces of the Tuileries, Saint Cloud, the Trianon, and the Château of Malmaison are open three days in the week, and those of Versailles, Fontainebleau, and Compiègne every day with the exception of Monday, unless the Emperor or Empress should be residing there.

The Imperial factories of Sèvres and the Gobelins are three times a week, the Louvre every day except Monday, the Museum of Cluny and the Ecole des Beaux-Arts every day without exception, the Sainte Chapelle and the Church of Saint Denis four times a week. The usual hours of admission are from eleven or twelve to four or five, but there are some exceptional cases. No passport, ticket, or permission is required in the case of any one of the above establishments, no fees are permitted to be taken by the attendants, and visitors may, if they please, retain their sticks or umbrellas in the Louvre or at Versailles.

The Trianon and Malmaison have been placed, under the direction of the Empress, as nearly as possible in the same state in which they were in the time of Marie Antoinette and the Empress Josephine, all the existing relics having been replaced.

museum of arms and armour in the Château of
onds has also been opened to the public on two
the week since the commencement of the present

Prefect of the Seine has decided that the cata-
shall be open every Saturday during the period of
hibition to all persons who may apply to the pre-
for tickets of admission.

ly, Prince Napoleon has thrown open his artistic
her collections in the Palais Royal five days in the
tickets to be had on application to the Prince's
e secretary, or to the Intendant of the Palais Royal.
may not be out of place, in connection with the
, to add that in a few days the restorations of the
or as well as of the exterior of the cathedral of
Dame will be completely finished. Much of the
ation of the choir, executed in the time of Louis
, has been replaced, including a marble group by
as Coustou; the statue of Louis XIII., by Guillaume
on; that of Louis XIV., by Coysevox; and six
es of angels. The mosaic pavement has also been
letely restored. The railings of the choir, of the
of Louis XIV., having been destroyed, they have
replaced by a new gilded iron screen bearing the
ers and emblems of Louis XIV. and Napoleon III.,
a Latin inscription describing the enclosure and
ration of the choir from 1163 to the present time.
carved stalls and other fittings and decorations have
been restored or replaced.

Fine Arts.

GIANT STATUE.—M. Lequesne, a French sculptor,
just received a commission to execute a statue of the
gin Mary nine metres, or very nearly 30 ft., high, for
bell-tower of the sanctuary of Notre Dame de la Garde,
Marseilles. There is to be a staircase within the
ue leading into the head itself, and the eyes, which
l serve as windows, through which to view the pros-
t around, will measure 10 inches.

ART EXHIBITIONS IN FRANCE.—A society of friends
art, authorised by the authorities of Upper Savoy,
nounces the opening of its first exhibition of works of
, to be held at Aix les Bains, from the 10th of July to
10th of August next, and afterwards at Chambéry,
on the 15th to the 26th of August; further, that the
society intends to make the Aix exhibition annual, and
transport it afterwards, alternately, to Chambéry and
necy, so that the exhibition will be biennial at the
ter places. This new society will not purchase any
orks of art, but will arrange a lottery of prizes of
rious amounts, leaving the winners to select their
ctures after the manner of the Art-Union of London.
he society undertakes the carriage of the works to the
hibition and back, and charges a commission of five
cent. on sales. A certain number of artists are
avited by circular to send works to the exhibition, but
there may send works, and if these are accepted by the
ociety for exhibition the same rules will apply as to
nvited exhibitors. Some other items in the regulations
re, perhaps, worth the consideration of local committees
and other bodies. It is laid down as a positive rule
hat each picture shall be fixed by screws within its
ase; that the interior of the latter shall be painted, and
its cover also fixed with screws, so that the picture may
be shown within its case. There are other conditions,
which may be learned of the secretary of the Société
des Amis des Arts de Savoie et Haute Savoie, Aix les
Bains.

Colonies.

TELEGRAPHS IN NEW SOUTH WALES.—The great line
which is to connect the capital of this colony with that

of South Australia is completed, and the superintendent
of telegraphs left Sydney for Adelaide, *via* Melbourne,
the 20th April last, to open this line. The opening of
this line will be a great convenience to those who are
accustomed to communicate by telegraph in both colonies,
and especially to the press, as the press messages, con-
taining the news from England by way of the branch
boat from King George's Sound, have hitherto come to
Sydney through Melbourne.

RATING IN VICTORIA.—A return of the number of
ratepayers in the city of Melbourne, the town of Geel-
long, and the fifty-nine boroughs of the colony of Vic-
toria, shows that the ratepayers on the rate last made are
72,827, of whom 52,800 are rated under £25; from £25
to £50, 10,510; from £50 to £100, 5,761; from £100 to
£150, 1,990; from £200 to £300, 645; at £300 and up-
wards, 586. The largest number of ratepayers is in
Melbourne, where they number 9,442. Next to Mel-
bourne follow the two boroughs of Ballarat West and
Ballarat East with 7,067, Sandhurst with 5,033, East
Collingwood with 4,445, Richmond with 3,687, Emerald-
hill with 2,746, Prahran with 2,523, Fitzroy with 2,434,
Hotham with 2,250, and St. Kilda with 2,007. The
shires and road districts number ninety-eight, with a
total number of ratepayers amounting to 52,456. The
total number is distributed as follows:—Those rated
under £25, 36,545; from £25 to £50, 8,981; from £50
to £100, 4,760; from £100 to £150, £1,326; from £150
to £200, 547; from £200 to £300, 437; upwards of
£300, 741.

TASMANIAN HOPS.—"The hop-growers at New Norfolk,
on the banks of the Derwent," the *Hobart Town Mercury*
remarks, "will do well this year. Last year they had
only 45 tons of hops; this year they calculate on 70 tons
—that is, an addition of 25 tons, or an increase of rather
more than one-third. Some years hops do not fetch
more than 9d. per pound; this year they are worth
1s. 6d. The consumption of hops in these colonies is
estimated at 1,000 tons a year, and this must be supplied
either by the home-grown or the imported article. As a
rule, the home-grown are preferred, chiefly on account
of the aroma being better preserved. They are fresher,
and do not require to be so densely packed, by which it
is reasonable to suppose that some portion of their virtue
is lost. There is, therefore, every encouragement for
an extension of the growth of hops in this country,
where the soil and climate are found to be so favourable
to them."

Notes.

INTERNATIONAL MONETARY CONFERENCE IN PARIS.—
The first meeting of this Conference took place at the
Ministry of Foreign Affairs, on the 18th June, under
the presidency of the Minister, the Marquis de Moustier.
The states represented were France, England, Austria,
Baden, Bavaria, Belgium, Denmark, Spain, United
States of America, Greece, Italy, Holland, Portugal,
Prussia, Russia, Sweden and Norway, Switzerland,
Turkey and Wurtemberg.

GRATUITOUS EDUCATION IN FRANCE.—The municipal
council of Orleans has, by the votes of 20 of its members
out of 28, decreed that from the first of October next
primary instruction shall be absolutely and uncondi-
tionally gratuitous in that town, the Maire and his three
deputies all voting for the proposition.

MEETINGS FOR THE ENSUING WEEK.

Journal of the Society of Arts.

FRIDAY, JULY 5, 1867.

Announcements by the Council.

MEETING OF COUNCIL.

Monday, July 1st, 1867.

At the first meeting of the present Council since their election, William Hawes, Esq., Vice-President of the Society, was unanimously elected *Chairman* for the current year.

SOCIETY'S VISIT TO THE PARIS EXHIBITION.

The Council have directed the Secretary to make arrangements for a visit of the members of the Society to the Paris Exhibition. The period fixed for the visit extends from Monday, the 29th of July, to Monday, the 12th of August. A reception-room has been provided for the use of the members during their stay, where their correspondence may be addressed, and where they will have the convenience of writing letters, making appointments with their friends, and where notices of all arrangements for visits to various places will be suspended. Lists of hotels and apartments will also be provided there for consultation.

A programme is in the course of preparation. Members contemplating visiting Paris at this time are requested to send in their names to the Secretary, in order that cards of membership and programmes may be furnished to them.

ARTIZANS' VISITS TO PARIS.

At the last and former International Exhibitions held in this country, arrangements were made by the French Government to facilitate the visits of skilled artizans, and interesting reports on the Exhibitions were made by them to their government. Believing that such visits on the part of skilled workmen to these great international displays not only exercise a beneficial influence upon the men themselves, but also upon the progress of industry in the country to which they belong, the Council have resolved to raise a fund to be employed in aiding a limited number of English workmen, specially selected from their respective trades, to proceed to Paris for the purpose of studying and reporting to the Society upon the relative merits of foreign and English workmanship, as represented at the present French Exhibition.

A considerable sum will be required satisfactorily to accomplish this object, and, in order to raise these funds, the Council have determined to appeal to the members of the Society and others to join in a subscription for the

furtherance of the undertaking; and they have decided to commence the subscription by a vote of one hundred guineas from the funds of the Society.

The Council have addressed a letter to Her Majesty's Commissioners for the Exhibition asking their assistance in obtaining pecuniary aid from the Government to enable them to realize their plan on a sufficiently extensive scale. Her Majesty's Commissioners thereupon passed the following resolution, which was proposed by Earl Granville, and seconded by Mr. Forster, M.P.:—"That the intention of obtaining reports by foremen and skilled workmen on their respective trades, on the occasion of their visiting the Paris Exhibition, is, in the opinion of Her Majesty's Commissioners, worthy of encouragement on the part of Her Majesty's Government."

This resolution having been transmitted by Her Majesty's Commissioners to the Lords of the Committee of Council on Education, their lordships have decided to "place at the disposal of the Society of Arts a sum not exceeding five hundred pounds, provided that the Society raises at least the same amount by voluntary subscriptions."

In order, therefore, that this grant may become available for the object in view, the Council venture to urge upon the members of the Society and others the importance of adding their names to the subscription list as early as possible.

The following is the list of subscriptions up to the present date:—

H.R.H. the Prince of Wales, President	..	£31	10	0

Subscriptions may be forwarded to the Financial Officer, at the Society's House.

The Council are now prepared to receive the names of any workmen recommended by their respective trades as fit and proper persons to undertake this important duty on behalf of their fellow workmen.

SUBSCRIPTIONS.

The Midsummer subscriptions are due, and should be forwarded by cheque or Post-office order, crossed "Coutts and Co.," and made payable to Mr. Samuel Thomas Davenport, Financial Officer.

Proceedings of the Society.

FOOD COMMITTEE.

A meeting of the Sub-Committee on Fish was held on Tuesday, 14th May:—Present, Mr. Benjamin Shaw in the chair; Mr. Caird, Mr. Ware, Mr. Michael, Professor J. Wilson, Captain Grant, and Mr. Ludford White.

Mr. CHARLES, of Pimlico, attended, and gave information with respect to the fish trade in London.

The CHAIRMAN, in the first place, called the attention of Mr. Charles to the alleged destruction of the fish by the salesmen in Billingsgate Market in the event of an over supply, in order to keep up the price of the article.

Mr. CHARLES—Had been a fishmonger many years and in a large way of business, and was well acquainted with the practice of the Billingsgate Market. He had a very large experience in the trade, and could state positively that no such thing ever occurred. He could not imagine such a thing as a salesman sacrificing a penny to benefit his neighbour a shilling. There was no union, he said, amongst the salesmen of Billingsgate for the purpose of keeping up prices, which were regulated by the supplies of each day's market. They all worked independently of each other. He gave his decided opinion that no wholesale destruction of fish, such as was alleged, ever occurred on the part either of the salesmen or the smack owners. Mr. Charles gave a brief history of the formation

of the Limited Liability Company known as Harland and Co., established for the purpose of bringing to the market in steam vessels in larger quantities and with greater despatch than could generally be accomplished by the ordinary fishing vessels.

In reply to questions with respect to the establishment of another fish market in the west of London,

Mr. CHARLES expressed a decided opinion against a proposition. He stated that the previous fish market which formerly existed near that spot (Hungerford) to a great extent a failure. The establishment of a market in the west of London would, he said, have the effect of dividing the buyers, and would involve a necessity on the part of persons like himself, of buying at each market, and the result might be a larger stock of a particular kind of fish might be procured than the retailer required for his trade, which would result in loss to him.

Captain GRANT explained that his own reason for establishing a fish market at the West-end was the large quantities of fish from the western coast being sent from the Great Western terminus, instead of the whole being conveyed as at present to Billingsgate, brought thence for distribution by the West-end. It appeared to him that considerable advantage was accrued both to the trade and to the public by the establishment of a fish market in some central locality of the West-end of London.

Mr. CHARLES said he would give the Committee reasons for believing that such a plan would not succeed. The fishing business, he remarked, was a proverbially uncertain one. It might happen that for days or weeks together the supply of all kinds of fish was small indeed, and it would not do to spread this over two markets. No dealer would think of going to the West-end market to buy his stock of fish. The existing system of the great fish market at Billingsgate there were certainly advantages both to the dealer and the public, as in the event of large quantities being brought into the market it was disposed of at lower prices. The article was one of a very perishable nature, and if spoiled was a total loss to the owner. Mr. Charles did not think that the establishment of a new market would lead to larger supplies being sent, but thought it would have no influence whatever upon the supplies. For instance, on that day a very large quantity of mackerel was received from Kingstown, near Dublin, which were brought by steamer to Milford Haven, and thence by the Great Western Railway to Paddington, and it was no more trouble to send the vans when they came to Billingsgate than it would be to take them to the West-end market, inasmuch as a journey from the station to the quarters of an hour to convey the whole lot of fish to Billingsgate. He was convinced, after considerable experience, that the multiplication of fish markets in London would be found to be a disadvantage rather than an advantage, and in his opinion it was quite impracticable to work such a system. Mr. Charles would further observe that two metropolitan fish markets would be disadvantageous to each other. The sensitiveness of buyers and sellers would delay business till the next day, the supply in each market could be compared; in the meantime the article would deteriorate in quality and value. The price, he said, varied 50 per cent. from day to day. Soles, which one day were sold at 6d. per lb., on the next day would fetch 1s. per lb. This was especially the case with regard to salmon. On the previous day he bought his salmon at 2s. per lb., that day it cost 2s. 6d. per lb. There was a smaller supply. The variation was sometimes as great the same day. It was practically sold by auction. The salmon was consigned to salesmen, who knew their customers, and who were able to buy it and who were not. Of course it was an open market, inasmuch as those who went with their cheque-book or cash had equal opportunities of buying, but it was a bad thing for those who wanted credit.

The CHAIRMAN then called the attention of Mr. Charles to the following passage from the Report of the Fisheries Commissioners:—

"The great importance of fish as an article of food may be clearly shown by a comparison of the total supply of fish and beef to London in the course of a single year. Neither in the case of fish, nor of beef, is it possible to give accurate statistics. But it has been roughly estimated that London consumes 300,000 fat cattle annually, which, at an average weight of 6 cwt. each, would amount to 90,000 tons of beef. At this moment there are between 800 and 900 trawl vessels engaged in supplying the London market with fish, and assuming the average annual take for each to be 90 tons, this would give a total of some 80,000 tons of trawled fish. This is irrespective of the vast quantities of herrings, sprats, shell-fish, and of other descriptions of fish which are supplied by other modes of fishing. The weight of beef and of fish annually consumed in London is thus in no great disproportion. But the price is very different. The fisherman receives, on an average, little over £7 a ton for his fish, prime and offal together,—the farmer is readily paid for his beef not less than £60 a ton. But this disparity of price becomes the more remarkable when tested by the practical experience, not of the producer but of the consumer. The buyer of fish in the West-end of London finds that, on the average, his fish costs him more per pound weight than his beef or mutton. And when inquiry is made, the salesman at Billingsgate readily admit that the retail dealer gets an enormous profit on the small quantity of fish he disposes of. It might be thought that the competition of trade would rectify any demand for excessive profit, but in this case it does not seem to have that effect. While the fishermen receive 3d. to 4d. a pound at Billingsgate for prime fish, the buyer is charged 1s., 1s. 3d., and 1s. 6d. a pound by the retailer."

Mr. CHARLES said he had read that report, and since receiving the invitation to attend before the committee, he had taken care to weigh several varieties of fish for their information. He would explain, first, with regard to trawl fish, that was brought to market now, whereas formerly it was not considered worth bringing. This remark especially applied to haddocks, from the great demand which existed for that article in a cured state. Formerly the great supply of that article was sent from Scotland, but the demand was so great that very large quantities were cured in London. Haddocks caught by the trawl used to be regarded as offal, and were the perquisites of the fishermen, who dried what they required in the rigging. The haddocks used for table were only those caught by the hook, though the fish were not so good as those which were trawled. The cause of the great difference of price was wholesale to the fishowners and that charged by the salesmen to their customers was from a large proportion of the fish being of an inferior quality, which was sold at a low price by the retailer, whilst the large proportion of fish required by such dealers as himself was of high quality. The low-priced fish reduced the average.

[Mr. Charles read from, and handed in to the committee, invoices of fish, showing the great variation in the price of salmon from day to day, as also of turbot, soles, &c. The difference in the price of salmon wholesale was shown to be as much as 8d. per lb., from one day to another.]

Mr. CAIRD remarked that the greatest fluctuations appeared to exist in salmon, which was not a sea-fish.

Mr. CHARLES said, even in sea-fish the fluctuations in price were very considerable. On that morning he was able to buy whittings at half the price he paid for them on the previous day. He bought them of a master fisherman, who sold his own goods, at 7d. per lb., which was equal to £65 8s. 8d. per ton, while salmon, at 2s. 1d. per lb. was equal to £233 6s. 8d. per ton; turbot at 6d. per lb. was equal to £56 per ton.

Mr. CAIRD remarked that it was very much the subject of complaint that the difference between the price charged to the customer and that paid to the salesman by the West-end dealers was very much greater than fair profits of trade required or justified.

Mr. CHARLES said the fact was not so. It was to be borne in mind that the fish was weighed to the dealer as it came into the market, including the offal, which, in some kinds of fish, amounted to a large proportion. The fish sold by retailers to their customers was sold free from all offal whatever, and in a clean state. In the preparation of whittings for table they lost nearly half their original weight. A fish which weighed one pound, when it was skinned and cleaned ready for table would not weigh much more, perhaps, than half a pound. It was, therefore, scarcely a fair way of putting it. As far as his own experience went, looking at the many expenses which the trade entailed, the profits of the retailers were by no means excessive, nor were they equal to those of many other trades in which the article dealt in was not of a perishable nature. He estimated that the profits upon all that passed through the hands of a dealer like himself would not be more than 10 per cent., which, looking to the expenses, could not be regarded as excessive. Personally speaking, he was satisfied with that amount of profit in his business.

The CHAIRMAN remarked that as compared with meat there was this difference, that nearly all the offal of an animal was turned into money by the retailer, which could not be the case with fish. Reverting to the question of a West-end fish market, he observed that at the present day Billingsgate could not be regarded as a central market for the metropolis.

Mr. CHARLES remarked he thought it was the best centre for the trade that could be found. Even London itself, he said, was not so central as it used to be for a fish market. Large quantities of fish were now sent direct from Hull to Ireland which used formerly to be sent to London.

Captain GRANT inquired whether the space for fishing vessels was not very restricted at Billingsgate?

Mr. CHARLES replied that there was generally plenty of room for the vessels. Such large quantities of fish were now sent by railway that there were not one-fourth of the vessels at Billingsgate which there used to be.

Mr. WARE called the attention of Mr. Charles to the following passage in the report of the Fisheries Commissioners:—

"The wholesale price realized for the two descriptions of fish by the fishermen is shown in the returns for five years, given by Mr. Knott. His average price per ton was about £7; but the price of the "prime" averaged £23, while that of the offal was only £2. It may indeed be said, broadly, that the main supply of the cheaper description of fish, which forms so valuable an article of food to the large masses of our population, is yielded by modes of fishing other than line-fishing, and that any attempt to restrict the industry of fishermen to that mode of capture would be certainly followed by an immediate diminution in quantity and increase in price of the coarser kinds of fish, and by a nearly total cessation of the supply of soles."

Mr. CHARLES observed that of the fish taken by the trawl, not a sixteenth could be estimated as prime fish. Large turbot were not now put upon the table; smaller sized fish were preferred, and while a turbot weighing 20lbs. or 24lbs. might be bought for 12s., as much as 8s. would be given for a fish of less than half that weight. With regard to the price of 2½d. per pound, or £23 per ton, for "prime," he could inform the committee that he had this year paid as much as 30s. each for cod fish; he was obliged to pay that price or go without; but he must have fish for his customers, whatever the price might be; and he might state that for every prime fish that came into the market there were ten buyers. The supply at present was generally nearly equal to the

demand, but there always had been ten buyers for every fish.

Professor Wilson suggested that that fact implied that the supply was not equal to the demand.

Mr. CHARLES said sometimes things were cheap; but there must be times when things were scarce, and then the prices went up. If the supply were doubled and trebled the consumption would take it up no doubt. He thought no limit could be placed upon it. If they could bring fish to £7 per ton there would be no limit to the demand for it.

Mr. LUDFORD WHITE remarked that it had been stated to the committee that fish was sometimes kept back at the port in order to keep up the prices.

Mr. CHARLES believed, if it was done at all, it was only to a limited extent. It might be the case that a very good cargo of fish might be divided over two markets—a portion being sent to-day and the remainder to-morrow; but that was not done to any great extent.

Mr. CAIRD asked whether Mr. Charles considered the supply at Billingsgate was increased or otherwise.

Mr. CHARLES replied it had diminished in his time; because London was not so central as it used to be, and the fish which used to be sent from Hull and Grimsby did not now come to London.

Mr. CAIRD further asked whether Mr. Charles was aware of any large increase in the investment of capital in the fishing trade in consequence of the increased demand of the London market?

Mr. CHARLES said no doubt there had been a large increase of capital employed in the trade, and the vessels engaged in it were worth a very considerable sum.

Proceedings of Institutions.

EAST LANCASHIRE UNION OF INSTITUTIONS.—The annual summer examination of this Union was held on Saturday, June 15, and attended by 129 candidates, of whom seventeen were females. The candidates met at nine o'clock, a.m., in the Assembly-room of the Mechanics' Institution, Burnley, and, with two hours' interval in the middle of the day, the examination lasted till five p.m. Arrangements were made by which those candidates who came from a distance were enabled to travel to and from Burnley for one fare. The pupils of the following Institutions competed:—Burnley Mechanics' Institution, Burnley Church Literary Institution, Bacup, Haslingden, Crawshawbooth, Rawtenstall, Newchurch, and Limeshaye. There are now two distinct annual examinations of the Union—a previous examination having been held at the end of March, for the last two years, for the convenience of those evening classes where the pupils disperse early in the spring. This examination is held at local centres, while the summer examination is held collectively at Burnley. The spring examination was attended by 100 candidates, of whom eighteen were females. The examinations have therefore been attended this year by 229 candidates, 194 males and 35 females, a larger number than in any previous year. After the examination on June 15th, Sir James Kay-Shuttleworth, Bart., the President of the Union, delivered an eloquent address to the candidates on the state of education in France and Prussia in comparison with that of England, and pointed out the urgent necessity for more attention to the secondary and technical education of the industrial population, if England is to keep pace with the Continental nations in inventive skill and manufacturing industry.

PARIS UNIVERSAL EXHIBITION.

The following are the particulars of prizes awarded to British exhibitors:—

In the fine arts department three prizes—Mr. Calderon,

A.R.A., taking a first, and Mr. E. Nicol and Mr. F. Walker each a second prize. In Class 3 Messrs. A. B. Wyon and J. S. Wyon obtained third class prizes; and in Class 4 a first prize was awarded to the late Captain Fowke, a second to Mr. W. D. Lyne, and a third to Mr. E. Barry.

In Class 5 (Engraving and Lithography) no prize was awarded to Great Britain.

Of the grand prizes six were awarded to British exhibitors. The following are the names of the holders of these prizes—Group I. (Class 4, Architectural Designs and Models), Mr. Waterhouse; in Group VI. (Class 64, Machine Tools), Mr. Whitworth; Class 64 (Telegraphic Apparatus), the Atlantic Telegraph Company, and Siemens Brothers, London; and in Class 66 (Navigation), the Lifeboat Society, Napier and Sons, Glasgow, and Penn and Co., Greenwich.

The following is a list of the awards to other British exhibitors:—

GROUP II.—APPARATUS AND APPLICATION OF THE LIBERAL ARTS.

CLASS 6.—Printing and Books.—Gold Medal—V. Brooks. Silver Medal—Bradbury and Evans, Cassell, Potter, and Galpin, Chambers, Hanhart, Illustrated London News, W. Mackenzie, Rowney, Spottiswoode and Co., Blake, Stephenson, Virtue and Co. Bronze Medal—William Bradbury, Butler and Tanner, Day and Sons, Pinks, Macdonald MacLure, Nelson and Sons, Wallis. Honourable Mention—Belous (Gloucester).

CLASS 7.—Paper, Stationery, Binding, Printing, and Drawing Materials.—Gold Medal—Cowan and Co. Saunders. Silver Medal—Brookedon, Crompton, Gillis and Co., Goodall, Hyde (ink), Hyde (wax), Letts and Son, Mordan, Portal (Laverstoke Mills), Riviere, Rowan, Stephens, Marcus Ward, Waterston. Bronze Medal—Alexandra Printing Ink Company, Bain, Beasley, Bridridge, Bell and Daldy, Blackie, Brookedon, Brown, Causton, Cohen, Day and Son, Eyre and Spottiswoode, Wells Hinks, Hughes and Kimber, Zaehnerdorf, Lamb, Lyon, Morley, Newman, Ramage, Reeves, Reynolds, Sampson Low, Smith and Elder, Team's Wood Pulp Company, Willey, Wills, Wolff.

CLASS 8.—Applications of Drawing and Modelling to the Common Arts.—Silver Medal—Lord Romilly, Society of Arts, J. S. and A. B. Wyon. Bronze Medal—Alldridge (Kensington Museum), Marcus Ward, Thomas Martin, Newman, Ortnor and Houle, Rooke, Ball Secres, Spinks. Honourable Mention—Jenner and Newstead, Master of the Rolls, A. Slater (South Kensington Museum).

CLASS 9.—Photograph Proofs and Apparatus.—Silver Medal—Bedford, Dallmeyer, England, Mudd, Robinson, Swann, C. T. Thompson, Woodbury. Bronze Medal—Blanchard, Briggs, Caldesi, N. K. Cherrill, Griggs, Joubert, Macfarlane, Mayall, Meagher, Ross, Tod, Vernon Heath, Wortley. Honourable Mention—Bentley, Beau, Browning, Cameron, Coghill, Cramb, Crick, Cruttenden, Hemphill, Hoemer, Pantooscopic Society, Pouncey, Ross, Rouch, Royal Artillery, Solomon, Swan, Thomas, Thompson, Verschoye, Wilson, Wordley.

CLASS 10.—Musical Instruments.—Gold Medal—Broadwood. Silver Medal—Bevington, Distin, Kirkman. Bronze Medal—Alison, Brinsmead, Bryceson, Ramsden, Wornum. Honourable Mention—Kelly, Leachman.

CLASS 11.—Medical and Surgical Instruments and Apparatus.—Gold Medal—Ash and Sons. Silver Medal—Evans and Stevens, Masters, Savory and Moon. Bronze Medal—Lemale, Longdon, Rein, Roth. Honourable Mention—Bacon, Earl of Caithness, Condy, Dickson, Marsden, Normans and Sons, Redford, T. P. Salt, Spence, Twinberrow, Wright.

CLASS 12.—Mathematical Instruments and Apparatus for Teaching Science.—Gold Medal—Beck, Chames, Dallmeyer, Ross. Silver Medal—Elliot, Ladd. Bronze Medal—Cole, Maru, Pauchett, Statham. Honourable Mention—Bethune, Crisp, Cronmire, Dunlop, Smith.

CLASS 13.—Maps and Geographical and Chronographic

Artis.—Silver Medal—Selwyn, Stamford. Honourable Mention—Bousquet, T. Nelson and Sons.

CLASS III.—FURNITURE AND OTHER OBJECTS FOR THE USE OF DWELLINGS.

CLASSES 14 AND 15.—Furniture and Upholstery and other Work.—Gold Medal—Owen Jones, Wright Linsfield. Silver Medal—Dyer and Watts, Gillow, and Trollope. Bronze Medal—Bettridge, Clayton Hall, Cole, Colman, Heal, Hunter, Ingledew, Jack (Rathbone-place), Lamb, Macdonald, Poynton, Poy, Taylor, Wedgewood, Wertheimer, Wyatt. Honourable Mention—Alderman, Benham, Ladyington, Cox, Filmer, Hayward, Skidmore, Ward. **CLASS 16.—Flint and other Glass; Stained Glass.**—Silver Medal—Dobson, Hardman, Powell. Bronze Medal—Airo and Calder, Edmundson, J. Green, and Pellatt, Ward and Hughes. Honourable Mention—Cottier, Cox and Son, Dury, Gardner, H. n, Lavers and Barraud, Millar, Newman, Phillips, 1-street.

CLASS 17.—Porcelain, Earthenware, and other Fancy wares.—Gold Medal—Copeland, Minton. Silver Medal—Brownfield, Doulton, Wedgewood. Bronze Medal—Gray, Jones, Pinder, Price, Primavici. Honourable Mention—Adams, Allen, Bishop's Wall, Clay Company.

CLASS 18.—Carpets, Tapestry, and Furniture Stuffs.—Silver Medal—Brinton and Lewis, Templeton. Silver Medal—Ackroyd, Henderson, Lapworth, Leather Cloth Company, Morton, Nairn, Patent Woollen Cloth, Wilson, Willis. Bronze Medal—Britannia Rubber Company, Deed, Firth, Humphries, Kohnstamm, Southwell, Fry Taylor, Templeton, Treloar, Woodward and sonner, Woodward, Palmer. Honourable Mention—ow, Hill, Hoff, Trestrail, Tull, Whincup, Whiteley, day.

CLASS 19.—Paperhangings.—Gold Medal—Potter. Silver Medal—Scott, Cuthbertson. Bronze Medal—W. ke, Jeffrey, Marsden, H. Woollams, J. Woollams. Honourable Mention—Horne.

CLASS 20.—Cutlery.—Gold Medal—Brookes and Stokes. Silver Medal—Morton. Bronze Medal—ppin, Webb, M'Daniel.

CLASS 21.—Gold and Silver Plate.—Gold Medal—ington, Hancock, Hunt and Roskell. Silver Medal—F. Emanuel. Bronze Medal—Mappin, Webb, Warston, Shaw and Fisher. Honourable Mention—anna, Hardman.

CLASS 22.—Bronze and other Artistic Castings and Related Work.—Nil.

CLASS 23.—Clock and Watch Work.—Gold Medal—lberg, Parkinson and Frodsham, Poole. Silver Medal—Adams, Blackie, G. Blackie, Dent, Mercer, Nicole and pt. Bronze Medal—Benson, Claxton, Holdsworth, hannsen, Sewell, O. Vivier, Walker, White. Honourable Mention—Howell and James, Webster.

CLASS 24.—Apparatus and Processes for Heating and Lighting.—Gold Medal—Winfield. Silver Medal—Ben- n, Bowser. Bronze Medal—Adams, Brown and rean, Leoni, Philp, Solomon, Musgrave, Woodcock. Honourable Mention—Barton, Best and Hobson, Dofries, rrest, Freeman, Glover (Pimlico), Huxhams and own, Leamington Range Company, M'Sherry, Ratcliff, eel and Garland, Stode, Sullivan, Young Brothers.

CLASS 25.—Perfumery.—Silver Medal—Atkinson. Bronze Medal—Cleaver, Pears, Perks, Picasse, Rimmell. Honourable Mention—Napoleon Price, Ransom, Remington.

CLASS 26.—Morocco Work, Fancy Articles, and Basket Work.—Silver Medal—Leuchars, Schaffar. Bronze Medal—Betjemann, Goggin, Jenner, Marcus Ward. Honourable Mention—Fenton, Howell and James.

GROUP IV.—CLOTHING, INCLUDING FABRICS, AND OTHER OBJECTS WORN ON THE PERSON.

CLASS 27.—Cotton Yarns, Threads, and Tissues.—Gold Medal—Armitage, Bazley, England and Scotland (col-

lection), Horrockses, Radcliff. Silver Medal—Barlow and Jones, Crewson, Hawkins, Kesselmeyer, Langworthy, Tolson. Bronze Medal—Christy, Faulkner, Clever (Manchester), Hall and Udall, Jabez Johnson. Honourable Mention—Martin and Johnson.

CLASS 28.—Flaxen and Hempen Yarns, Threads, and Tissues.—Gold Medal—"Belfast," Brown, Charley, Fenton. Silver Medal—Matier. Bronze Medal—Glasgow Jute Company. Honourable Mention—Ainsworth, Pegler.

CLASS 29.—Combed Wool and Worsted Yarns and Fabrics.—Gold Medal—Ackroyd, "Bradford." Silver Medal—Middleton, Mitchell and Shepherd, Willett. Bronze Medal—Smithson, Taylor.

CLASS 30.—Curled Wool and Woollen Yarns and Fabrics.—Gold Medal—"South of Scotland," "West of England." Silver Medal—Batley Chamber of Commerce, Bliss, J. and H. Brown, Clay, Davies and Sons, Geissler, Houston, Jowling, Laverton, Lawton, Marling and Co., Leonard Marling, Naish, Salter, Strachan, Taylor Brothers. Bronze Medal—Barnicott, Binns and Godfrey, Birchall, Byers, Carr, Colson and Co., Howgate Day, Watkinson Day, Nicholls Dixon, Firth, Hall and Frater, Haigh, Hargreave, Harrison, Hunt and Winterbotham, Laing and Irvine, Mahoney, Mellor, Riley, Sanderson, Scott and Sons (Morley), Smith and Sons (Morley), Stockdale, Taylor and Lodge, Thackral, Thomson and Dodd, Vickerman, J. Walker and Sons, Wilson (Kendal). Honourable Mention—Cambrian Flannel, Crowther and Sons, Glendinning, Hogg M'Intyre, Kershaw (Rochdale), Lenthly, Scholefield, R. Scott, W. Scott, J. Scott and Sons, Stockwell, Wade, Walton and Rhodes.

CLASS 31.—Silk and Silk Manufactures.—Gold Medal—Collective British. Silver Medal—Birchenough, Nicholson Brough, Carter and Phillips, Cortauld, Franklin, Fry and Co., Grout, Seamer, Slater, (Buckingham), Spires, Taylor and Stokes. Bronze Medal—Carr and Co., Chadwick, Coventry Elastic, D. Evans, Hart, Hodges (Leicester), Lister, Norwich Grape, Posselt, Wanklyn. Honourable Mention—Grant and Gask, Hall and Udall, George Holme, Kay and Richardson, Kesselmeyer, Groenhalgh, Peel, Turner, Barrs and Co.

CLASS 32.—Shawls.—Silver Medal—Scott Kerr. Bronze Medal—Bliss, Brigg. Honourable Mention—Hitchcock Williams, Johnstone, Manby, Romanes and Paterson, Smith.

CLASS 33.—Lace, Net, Embroidery, and Trimmings.—Gold Medal—"Nottingham." Silver Medal—Copestake, Hartshorn, Hayman and Alexander, Jacoby. Bronze Medal—Allen (Dublin), Barnett and Maltby, Dunicliffe, Mary Jones, Lester, Manlove Packer, Tredwin. Honourable Mention—Mrs. Alderson, Davies and Co. (St. Martin's-lane), Miss Maclean.

CLASS 34.—Hosiery, Under-Clothing, and Minor Articles.—Gold Medal—Hogg M'Intyre. Silver Medal—Plant (Leicester), Smyth (Dublin). Bronze Medal—Coles, Martin, Pentony, Swears and Wells, Sweetman. Honourable Mention—De Becker, Jowett, Lane.

CLASS 35.—Clothing for both Sexes.—Silver Medal—Christy, Lobb, Player, Vaseo. Bronze Medal—Atloff and Norman, Carles, Craig, East, Glow, Hall, Melton, Brown Munt, Tait, Tress, Welch, Wilhelm. Honourable Mention—Ashton, Bowley, Grant, Hall (Hats), Hall (Sparkes), Mole, Norman, Wilson (Newcastle).

CLASS 36.—Jewellery and Ornaments.—Gold Medal—Phillips. Silver Medal—Brogden, Emanuel, Hancock, Hunt and Roskell, Randal (Birmingham). Bronze Medal—Crouch, Howell and James, Jacob, Lund, Marshall, Watherston. Honourable Mention—Neul, Thomas, Turnbull, Wheatley, Wiley.

CLASS 37.—Portable Arms.—Silver Medal—Greener, Lang, Reilly, Small Arms Company, Whitworth. Bronze Medal—Gibbs, A. L. Gibbs. Honourable Mention—Dougall, Ludlow, Prentice.

CLASS 38.—Travelling and Camp Equipages.—Silver

Medal—Cave, Wilkes. Bronze Medal—Silver. Honourable Mention—Bussey Smith.

CLASS 39.—*Toys*.—Silver Medal—Cremor.

GROUP V.—*PRODUCTS, RAW AND MANUFACTURED, OF MINING INDUSTRY, FORESTRY, &c.*

CLASS 40.—*Mining and Metallurgy*.—Gold Medal—Barrow (Alverston), Bowling Iron Co., Brown (Sheffield), Burys (Sheffield), Johnson, Matthey and Co., Lilleshall, Low Moor, Monkbridge Co., Turton. Silver Medal—Bartlett, Beard and Sons, Boulton, Comfort, Dowlais, Eagle Iron Co., Evans and Askin, Everett, French Jewellery Co., Gilpin, Hart and Sons, Johnson and Nephew, Kirby, Beard, Lloyd and Lloyd, Loveridge, Patent Bolt and Nut, Plumbago, James Russell, John Russell, Sharp, Brown, Taylor Brothers, Tonks, West Cumberland, Whitley. Bronze Medal—Aberdare, Addis, Baugh, Botts, Birmingham Iron and Brass Tube Company, Blaenavon, Bodrington, Broughton Company, Bwlla, T. Clark and Co., Elliott's Company, Davis (Cardiff), English and Australian Copper Company, Green's Tube Company, Greening, Haswell Coal Company, Heeley, Hill (Birmingham), Dr. Honeyman, Field, Macdonald, Martineau and Smith, Moreton (Wolverhampton), Millward (Redditch), Morewood and Rogers, Page, Reckitt, T. Smith and Co., Stickley, Walker and Parker, Webster and Horsfall, Wigan Company, Zobel, Townsend and Co. Honourable Mention—Abbott, Bankart, Barnes, Benham, Braby, Brotherton, Dollar Brothers, Green, Gregory, Hayes and Bennett, Heath, J. V. Hill, James Foundry, Leach, Martin, Millward (Birmingham), North of England Forged Nail and Rivet Company, Perrons and Harrison, Pratt, Smith (Leicester), Sparkes, Stanley, Taliaka Mining Company, Tudor, Earl Vane, Vickerman, Walton, Whiteway, Ystafera.

CLASS 41.—*Forest Products and Industries*.—Bronze Medal—South Kensington.

CLASS 42.—*Products of the Chase and Fisheries; Uncultivated Products*.—Silver Medal—Bovington, Deed and Ward. Honourable Mention—Du Costa.

CLASS 43.—*Agricultural Products (not used as Food) easily Preserved*.—Silver Medal—St. Ann's Model Farm, Neighbour. Bronze Medal—Bickersteth, Collier, Davis, Evans and Stafford, Kirckclin, Morton, Raynbird, Thompson, Windle, Woollerton.

CLASS 44.—*Chemical and Pharmaceutical Products*.—Gold Medal—Allhusen, Gossage, Howard, Jarro Company Muspratt, Price's Company, Young's Paraffin. Silver Medal—Bailey, Bewicke, British Seaweed, Calvert, H. B. Condy, Cow, Hill, Denton and Jutsum, Demuth, Field, Gaskill, D. and W. Gibbs, Hopkin and Williams, Hurlst Alum Company, Johnson and Matthey, Knight, Macfarlane, Mander Brothers, Mawson, Ogleby, Parkes, Rose, Smith, Tudor, Walker Alkali Company, Warne, Wilkinson. Bronze Medal—Adams, Baker and May (Class 30), Britannia Rubber, Burgoyne, Bush, Calley, Clarke, W. Cook and Co., Danley, Davy, Yates and Routledge, Day and Martin, Dodge, Garrod, Goodwin, Green, Haas and Co., Hodgson and Simpson, Holland, Hosegood, Huskisson, C. Jarro, Langton and Bickells, Lamb and Sterry, Lange and Moselle, Lowe (Manchester), McDougall, McKay, Mason, Nimmo, J. N. Parker and Co., Pulford, W. Ransome, Rogers, Rumsey, Squire, Stephens, Talbot and Alder, W. Taylor and &c., Turner and Son, Wandle, Waring.

CLASS 45.—*Specimens of the Chemical Processes used in Bleaching, Dyeing, Printing, and Dressing*.—Silver Medal—Hinds, Ripley. Bronze Medal—Barlow, Dickens, Howe. Honourable Mention—Whincup.

CLASS 46.—*LEATHER AND SKINS*.—Silver Medal—Dixon, Evans, Flitch, Puckridge, Wilson, Walker, Winter and Masters. Bronze Medal—Doed, Pullman. Honourable Mention—Bayley, Brearly, Webb.

GROUP VI.—*APPARATUS AND PROCESSES USED IN THE COMMON ARTS.*

CLASS 47.—*Apparatus and Processes of Mining and*

Metallurgy.—Silver Medal—Carrett, Marshall, Jones and Levick. Bronze Medal—Bickford, Smith, Twyler. Honourable Mention—Beaumont and Locock.

CLASS 48.—*Implements and Processes used in the Cultivation of Fields and Forests*.—Gold Medal—Clayton, Fowler, Garrett, Hornsby, Howard, Ransomes. Silver Medal—Aveling, Benthall, Coleman, Marshall, Penny, Pixley, Reading Company, Richmond, Robey, Samsel, Smith (Peasenhall), Turner. Bronze Medal—Ashby, Bamlett, Kearsley, Nicholson, Ruston, Smith (Kettering), Wallis, Woods. Honourable Mention—Amies, Ball, Brown and May, Fox, Walker, Parks, Palmer, Underhill.

CLASS 49.—*Implements used in the Chase, Fisheries, and Gathering Wild Products*.—Silver Medal—Aldred, Beard, Kirby, Irish Fisheries. Bronze Medal—Bartlett, Milward. Honourable Mention—Buchanan, Ryder.

CLASS 50.—*Apparatus and Processes used in Agricultural Works, and for the Preparation of Food*.—Silver Medal—Atmospheric Churn, Bradford, Clayton, Spencer. Bronze Medal—Collier, Fleet, Kent, Loftus Parkes, Lyon, Pontifex, Robinson, Silicated Filter, Tye, Whitehead. Honourable Mention—Barnett, Bawden, Canadian Company, Carson and Toone, Clark and Duham, Furrow and Jackson, Hickling, Keith, Summerscales, Weham Lake, Williamson.

CLASS 51.—*Apparatus used in Chemistry, Pharmacy, and Tanning*.—Gold Medal—Johnson, Matthey and Co. Silver Medal—Cocks, Plumbago Company. Bronze Medal—Doulton, Hynam, Porter. Honourable Mention—Baker, Bower, Carr, Cliff, Huxhams and Brown, Kent, Wilson.

CLASS 52.—*Prime Movers, Boilers, and Engines, specially adapted to the Requirements of the Exhibition*.—Silver Medal—B. Donkin, Fox, Walker, Galloway, Hilda Hargreaves, Porter. Bronze Medal—Appleby, Sharp, Stewart.

CLASS 53.—*Machines and Apparatus in General*.—Gold Medal—Merryweather. Silver Medal—Carrett, Marshall, Donkin, Eades, Glover and Co., S. Glover, Gwynne, C. Lloyd, Pooley and Sons, Reading Company, Shand and Mason, Tangye, Weston. Bronze Medal—Baines, E. Defries, Electro-Magnetic Company, Gas Meter Company, E. Green and Son, Kennedy, Marshall, Sons, and Co., Paul, Royal Life Protection Society, Sugg, West and Gregson, Williamson, North Moor Foundry Company. Honourable Mention—Bastier, Bernays, Dailson, Dewrance, Duckham, J. C. Hill and Co., T. Lambert and Sons, Leoni, Newton and Bradcock, Swann, R. W. Thomson, Warne, Westminster and London Meter Company.

CLASS 54.—*Machine Tools*.—Gold Medal—Hill Shepherd, Stewart, Sharp. Silver Medal—D. Davies, D. Bergen, Tannett, Walker, Thwaites and Carbutt, Worsam. Bronze Medal—Bass, Clayton, Massey, Neilson, Charles Powis, Powis and James, Robinson (Rochdale), Whitehead (Preston). Honourable Mention—Easterbrook, Sketchley, Rhodes.

CLASS 55.—*Apparatus and Processes used in Spinning and Rope Making*.—Gold Medal—Lawson, Platt. Silver Medal—Brook, Combe, Horsfall, J. and S. Smith Wren. Bronze Medal—Booth, Dixon, Irvine, Lewis Watkins. Honourable Mention—Hodgkin, Mallinson.

CLASS 56.—*Apparatus and Processes used in Weaving*.—Gold Medal—Howard and Bullough, Leeming, George Hodgson. Silver Medal—Hall (Bury), Hattersley, Keighly, Parker, W. Smith and Brothers. Bronze Medal—Cooke and Hacking, Ferrabee, Sowden and Stephenson, Lindsay Urquhart. Honourable Mention—Ingham, Salter.

CLASS 57.—*Apparatus and Processes for Sewing and for Making up Clothing*.—Silver Medal—Thomas Wamser. Bronze Medal—Newton Wilson, Simpson, Turner. Honourable Mention—Alexandra, Clements, Pitt.

CLASS 58.—*Apparatus and Processes used in the Manufacture of Furniture and other Objects for Dwellings*.—Nil

CLASS 59.—*Apparatus and Processes used in Paper-making, Dyeing, and Printing.*—Silver Medal—Boileau. Bronze Medal—Robinson. Honourable Mention—Stones.

CLASS 60.—*Machines, Instruments and Processes used in various Works.*—Nil.

CLASS 61.—*Carriages and Wheelwrights' Work.*—Gold Medal—Peters. Silver Medal—Aldebert, Cockshott, Cole, Holmes, Lawrie, Mason, E. and G. Morgan, Rock, Ward, Woodall, Wyburn. Bronze Medal—Evans, Fuller, Hutton, Ivall, M'Naught and Smith, F. Mulliner, H. Mulliner, Offord, Starey, Thorn, Windover. Honourable Mention—Cooper, Davies.

CLASS 62.—*Harness and Saddlery.*—Silver Medal—Haynes, Swayne. Bronze Medal—Bliss, Hampson, Martin, Shammoun. Honourable Mention—Aldred, Blackwell, Cuff, Eilam, Head, Jassman, M'Cracken.

CLASS 63.—*Railway Apparatus.*—Gold Medal—Kitson, Sanby and Farmer, R. Stephenson. Silver Medal—Lilleshall, Pooley (Liverpool), Turton. Bronze Medal—Alice Gordon, Lavesay, Preece, Spencer (Newcastle). Honourable Mention—Dering, Fairlie, Hughes, Ruston, Proctor.

CLASS 64.—*Telegraphic Apparatus and Processes.*—Gold Medal—Henley, Hooper. Honourable Mention—Nicoll.

CLASS 65.—*Civil Engineering, Public Works, and Architecture.*—Gold Medal—Chance Brothers, Minton. Silver Medal—Blanchard, Blashfield, Chubb, C. B. Cole, J. Clift and Son, Deulton, Hobbs, Jennings, Maw and Co., Peake, Pulham, White Brothers. Bronze Medal—Brooks, Chatwood, Clark's Blinds, Colthurst, Eassie, Gallichan, Gotto, Greaves, Macdonald, Norman, F. Ransome, A. Robinson, Sissons and White, Welch Slate Company. Honourable Mention—Cooke, Sandham, Lord Willoughby.

CLASS 66.—*Navigation and Lifeboats, Yachts, and Pleasure Boats.*—Gold Medal—Clarke (Great George-street), Humphries and Tennant, Laird Maudsley, Randolph, Samuda, Thames Iron Works. Silver Medal—Colomb, Denny, Gisborne, Halstead, Martin, C. Mitchell, Palmer's Company, Ravenhill, Rennie, J. S. White. Bronze Medal—Bolton, Clifford, Gourlay, Harfield, I. Harvey and Co., Hurst, Huxhams and Brown, Inglis, Lloyd's Register, Matthew, Oswald, Richardson, Duck, J. Taylor and Sons, Ward. Honourable Mention—Daft, Hay, Lumley, Ritchie, Tucker, Walker, W. H. Walker, Wisbart.

GROUP VII.—*FOOD, FRESH OR PRESERVED, IN VARIOUS STATES OF PRESERVATION.*

CLASS 67.—*Cereals, and other Eatable Farinaceous Products, with their Derivatives.*—Silver Medal—Berger, Orlando Jones, Raynbird, Reckitt. Bronze Medal—Steward (Bristol), File (Whitby).

CLASS 68.—*Bread and Pastry.*—Silver Medal—Huntley, Peek, Freen.

CLASS 69.—*Fatty Substances used as Food—Milk and Eggs.*—Nil.

CLASS 70.—*Meat and Fish.*—Silver Medal—Morton.

CLASS 71.—*Vegetables and Fruit.*—Silver Medal—Crosse and Blackwell. Bronze Medal—Batty, Burgess.

CLASS 72.—*Condiments and Stimulants; Sugar and Confectionery.*—Silver Medal—Colman, Fry, Salt (Chamber of Commerce). Bronze Medal—Batty, Crosse, Keen. Honourable Mention—Burgess, Gatti.

CLASS 73.—*Fermented Drinks.*—Gold Medal—Allsopp, Bass. Silver Medal—Aitchison, Ballingall, Burton Brewery.

GROUP VIII.—*LIVE STOCK AND SPECIMENS OF AGRICULTURAL BUILDINGS.*

CLASS 74.—*Form Buildings and Agricultural Works.*—Nil.

CLASS 75.—*Horses, Asses, Mules.*—Nil.

CLASS 76.—*Bulls, Buffaloes, &c.*—Nil.

CLASS 77.—*Sheep, Goats.*—Nil.

CLASS 78.—*Pigs, Rabbits.*—Nil.

CLASS 79.—*Poultry.*—Nil.

CLASS 80.—*Sporting Dogs and Watch Dogs.*—Nil.

CLASS 81.—*Useful Insects.*—Nil.

CLASS 82.—*Fish, Crustacea, and Mollusca.*—Nil.

GROUP IX.—*LIVE PRODUCE AND SPECIMENS OF HORTICULTURAL WORKS.*

CLASS 83.—*Glass Houses and Apparatus.*—Nil.

CLASS 84.—*Flowers and Ornamental Plants.*—Nil.

CLASS 85.—*Vegetables.*—Nil.

CLASS 86.—*Fruit Trees.*—Nil.

CLASS 87.—*Seeds and Saplings of Forest Trees.*—Nil.

CLASS 88.—*Hot House Plants.*—Nil.

GROUP X.—*ARTICLES EXHIBITED WITH THE SPECIAL OBJECT OF IMPROVING THE PHYSICAL AND MORAL CONDITION OF THE PEOPLE.*

CLASS 89.—*Apparatus and Methods used in the Instruction of Children.*—Silver Medal—Christian Knowledge Society, Home and Colonial, John Hullah, Sunday School Union. Bronze Medal—Oliver and Boyd, Williams, Winsor. Honourable Mention—W. Stevens.

CLASS 90.—*Libraries and Apparatus used in the Instruction of Adults, at Home, in the Workshop, or in Schools and Colleges.*—Gold Medal—Book Hawking Union, South Kensington. Honourable Mention—Crommire, Wright.

CLASS 91.—*Furniture, Clothing, and Food from all sources, remarkable for useful qualities combined with cheapness.*—Honourable Mention—Harry Taylor.

CLASS 92.—*Specimens of the Clothing worn by the people of different Countries.*—Nil.

CLASS 93.—*Examples of Duellings characterised by cheapness, combined with the condition necessary for health and comfort.*—Bronze Medal—Lord Digby.

CLASS 94.—*Articles of all Kinds manufactured by Working Masters.*—Nil.

CLASS 95.—*Instruments and Processes peculiar to Working Masters.*—Nil.

The Emperor distributed the prizes at a grand ceremonial in the Palais de l'Industrie on Monday last, the 1st instant. His Imperial Majesty delivered the following speech:—

"Gentlemen,—After an interval of twelve years I have come for the second time to distribute the rewards to those who have most distinguished themselves in those works which enrich nations, embellish life, and soften manners. The poets of antiquity sung the praises of those great games in which the various nations of Greece assembled to contend for the prizes of the race. What would they say to-day were they to be present at these Olympic games of the whole world, in which all nations, contending by intellect, seem to launch themselves simultaneously in the infinite career of progress towards an ideal incessantly approached without ever being able to be attained? From all parts of the earth the representatives of science, of the arts, and of industry, have hastened to vie with each other, and we may say that peoples and kings have both come to do honour to the efforts of labour, and to crown them by their presence with the idea of conciliation and peace. Indeed, in these great assemblies, which appear to have no other object than material interests, a moral sentiment always disengages itself from the competition of intelligence—a sentiment of concord and civilisation. In drawing near, nations learn to know and to esteem each other; hatred is extinguished, and the truth becomes more and more evident that the prosperity of each country contributes to the prosperity of all. The Exhibition of 1867 may justly be termed universal, for it unites the elements of all the riches of the globe; side by side with the latest improvements of modern art appear the products of the remotest ages, so that they represent at one and the same time the genius of all ages and of all nations. It is universal, for, in addition to the marvels luxury brings forth for the few, it displays also that which is demanded by the necessities of the many. The interests of the la-

bouring classes have never aroused more lively solicitude. Their moral and material wants, their education, the conditions of life at a cheap rate, the most productive combinations of association, have been the object of patient inquiries, of serious study. Thus all improvements march forward. If science, by turning matter to account, liberates labour; the cultivation of the mind, by subduing vices, prejudices, and vulgar passions, also liberates humanity. Let us congratulate ourselves, gentlemen, upon having received among us the majority of the sovereigns and princes of Europe, and so many distinguished visitors. Let us also be proud of having shown France as she is—great, prosperous, and free. One must be destitute of all patriotic faith to doubt of her greatness; must close one's eyes to evidence to deny her prosperity; must misunderstand her institutions, tolerant sometimes even of license, not to behold in them liberty. Foreigners have been able to appreciate this. France—formerly disquieted, and casting out her uneasiness beyond her frontiers—now laborious and calm, always fertile in generous ideas, turning her genius to the most diverse marvels, and never allowing herself to be enervated by material enjoyments. Attentive minds will have divined without trouble that notwithstanding the development of wealth, notwithstanding encitements towards prosperity, the fibre of the nation is always ready to vibrate as soon as the question of honour and the country arises; but this noble susceptibility could not be a subject of alarm for the repose of the world. Let those who have lived for a short time amongst us carry to their homes a just opinion of our country; let them feel persuaded of the sentiments of esteem and sympathy we entertain for foreign nations, and our sincere desire to live at peace with them. I thank the Imperial Commission, the members of the jury, and the different committees, for the intelligent zeal they have displayed in the accomplishment of their tasks—I thank them also in the name of the Prince Imperial, whom, notwithstanding his tender age, I have been happy to associate in this great undertaking, of which he will retain the remembrance. I hope the Exhibition of 1867 will mark a new era of harmony and of progress. Assured that Providence blesses the efforts of all who, like ourselves, desire good, I believe in the definitive triumph of the great principles of morality and justice, which, while satisfying all legitimate desires, are alone able to consolidate thrones, to elevate nations, and to ennoble humanity."

THE MACHINERY AT THE PARIS EXHIBITION.

The arrangements for ventilating the building consist in a system of circular and radiating underground galleries. The 16 radiating galleries communicate with the outer air by means of 16 air shafts, down which the air is drawn by the assistance of the artificial current produced by an air jet placed in each of these radiating galleries, and distributed throughout the building by means of a number of air-grates in the flooring. The compressed air is supplied to these air jets through pipes, varying in diameter from one to two feet. The quantity of air passing through the jets is regulated by a valve in form of a disc, the maximum opening of which is 130 square centimetres, with a speed of 6 ft. 6 in. per second.

The total force employed in compressing air is 105 nominal horse power, arranged as follows:—

The first is a 15-horse power portable engine, by Messrs. Farcot and Sons, of St. Onen, driving two air-fans, constructed by M. Perrigault; these supply two air jets. The next four air jets are supplied by a horizontal engine of 25-horse power, by Messrs. Gargan, of Paris, working three exhausting cylinders, 2' 8" in diameter, with 2' 4" stroke, situated in the Belgian boiler-house. Four other air jets are supplied by two large air fans, by M. Perrigault, from the shafting in the Austrian

section of the machinery gallery, driven by a horizontal engine of 25-horse power. The air is supplied to the remaining six air jets by means of blowing cylinders, 4 ft. in diameter, with 2' 8" stroke, by Messrs. Gaudier and Phillipon, driven by horizontal engines of 40-horse power, situated in the park, near the Egyptian temple.

The spinning and weaving machinery occupies a large space in the French section. Messrs. Stehelin and Co., of Bitchwillor (Haut Rhin), exhibit a self-acting mule for cotton-spinning, with 442 spindles. The cotton passes from the bobbin between four rows of rollers to the spindles; the end pair of rollers only are weighted. To give increased steadiness to the carriage, its back forms in plan a parabolic curve, instead of the back and front being parallel, as in those generally in use. They also exhibit a highly ingenious circular wool-combing machine. The wool, in ten or more slivers, is fed in between a pair of fluted rollers; it is then led forward by an endless chain of combs, arranged in a highly ingenious manner, on which it is placed by a descending brush; from this it is seized by a pair of jaws, that take it forward, and from these it is taken by a comb, and placed on the revolving circular comb; the long fibres which project outside the tooth are guided, by an endless leather strip, to a pair of fluted rollers, where a sliver is formed, and passed through the centre of a revolving hollow cone into a can; the short wool remaining between the teeth of the comb is cleared out by means of triangular plates, and passed off between fluted rollers to another can.

Messrs. Morel and Co., of Roubaix (Nord), also exhibit a circular wool-combing machine. The slivers supplied from fifteen bobbins are brought forward over the circular horizontal revolving comb, when the wool is seized by a pair of jaws and placed on the teeth of the comb by a descending brush; the long fibres that remain outside the comb are guided by an endless band of leather between fluted rollers, and the sliver thus formed is led away to the can. In this machine there are two feeds opposite each other, and two slivers of long wool are formed on each side. The short wool is guided from between the combs by triangular cleaners and taken to cans. The circular comb is formed of eight concentric rows of teeth placed on a revolving cylinder, inside of which a projection is cast, forming cam motions, by which the jaws and brush receive their respective movements.

A most effective machine is exhibited by M. Buzon, for preparing woollen or other rags for recarding or for paper making. The rags are fed, by means of an endless feed-cloth, between iron rollers, the bottom one of which is covered with india rubber, within range of a drum making about 1,000 revolutions per minute, covered with steel teeth, resembling those of a circular saw; the top feed roller is kept clear by means of a knife, which prevents the wool being wrapped round it. The drum is cleared of wool on the delivery side by a circular brush. This machine requires about 1½ horse power, and prepares from 300 lbs. to 400 lbs. per day.

M. Vouillon, of Louviers (Eure), shows a machine for the production of "fils feutres," threads which are not spun but felted. The thirty slivers from the condenser are passed, on an endless felt band, covered with linen, under four wooden rollers covered in a like manner. These rollers have a backward and forward motion across the endless band which rubs the slivers into yarn. A steam-pipe is introduced between the first two rollers, for the purpose of heating the wool, in order to facilitate the operation of straightening the fibres.

Messrs. Radiquet and Lecène, of Paris, exhibit several circular stocking frames, in which, by aid of electricity, when a thread breaks the machine is stopped.

A highly ingenious machine for making fishing-net is exhibited at work, by Messrs. Jouanin and Co., of Paris. In this machine the bobbins containing the warp are placed on a frame at the back of the machine, and correspond with the number of meshes in the width of the

net; it passes over guide-pulleys, so arranged as to keep the threads in a horizontal line, to a roller round which it is wound once, at the front of the machine. In the interval between the guide-rollers and the front roller is a sinker, formed of a horizontal bar, carried by two levers on a rocking shaft, and so counterbalanced as to take up any slack in the warp-thread, and yet to rise when the threads are pulled very tight, as is done in a certain part of the knotting process. The loops of the warp are engaged by a row of horizontal hooks, each of which works upon its axis by means of a long rack. The weft-thread, which is contained in a row of spools placed each in a sort of shuttle in front of the machine, is passed through the loops previously formed in the warp, and in this manner the knot is formed, each shuttle being so guided by the frame by which it is moved to form its proper knot and mesh. This machine works with such precision that the thread is never frayed, and the knot of the mesh is never too tight; this is considered to be an advantage for the operation of tanning, the liquid being able to soak in more readily. The speed of this machine is twelve revolutions per minute, which would give 7,920 rows of knots in a day of eleven hours if the machine were not stopped for the re-filling the spools.

Messrs. Schneider, Legrand, Martinot, and Co., of Sedan (Ardennes) show a machine for calendaring or preparing cottons or linens for the calico-printer, in which the fibrous down is removed from the surface of the cloth by passing the piece rapidly over the surface of a series of steel plates, with small teeth; these blades act in the same manner as saws, and have a backward and forward motion across the piece, which is drawn over them at the rate of 450 yards per hour. The first blades have 30 teeth to the inch, and the finishing blades 40 to the inch.

The same firm also exhibit a shearing machine and a teasing machine for cloths and woollens.

Messrs. Hermann, Devinck, Debattiste all exhibit excellent machinery for grinding and preparing chocolate. In the machines constructed by the first, the table and stones are all in granite.

The motive power in the Belgian section has been supplied by Messrs. Houget and Teston, of Verviers, from whose plans the boilers were constructed by Messrs. Petry and Chandoir, of Liège. Each boiler is constructed with the grates leading into the same combustion chamber, and, if care is taken in firing alternately each furnace, the smoke produced by the fresh combustion is burnt. The gases thus pass through the tubes, of which there are 75. The engine supplied by Messrs. Houget and Teston is of 50 nominal horse power. It has two horizontal cylinders, and can be worked either with or without the condenser. The shaft is well balanced by a fly-wheel at each extremity, and the whole is very compact.

Messrs. Houget and Teston also exhibit in motion a series of machinery for preparing wool for spinning; and their carding engines, fitted with Messrs. Apperley and Clissold's diagonal feeders, are of excellent workmanship. The object of this feeder is to lay and deliver the fibres crosswise to the finisher card, to be again straightened by the taker-in rollers. The same firm also show shearing and fulling machinery for cloths and woollen goods. M. Celestin Martin, of Verviers, also exhibits highly ingenious machinery for the preparation and spinning of wool. The first machine, for the purpose of cleaning and oiling the wool preparatory to being carded, is very complete. From this it is taken to the first carding engine and formed into a single sliver or ribbon; forty of these slivers are then transferred to the second carding engine and formed into a single ribbon. This sliver—of larger size than the previous one—is laid backwards and forwards across the endless lattice of the condenser, so as to form a continuous fleece. The novelty in this machine is the mode of dividing the fleece. This is effected by steel springs placed between the cylinder and the

doffer, and the strips pass between two endless bands of leather or rubbers, having an alternate motion across the threads. This machine forms 60 good threads and two wasters at each side. An excellent self-acting mule is also exhibited by this firm.

A colliery winding engine of 200 horse power is exhibited by Messrs. Dorzé and Andry, of Boussu, near Mons.

The Society John Cockerill, of Seraing, exhibit a vertical blowing engine for blast purposes; the blowing cylinder is nine feet in diameter.

In the Prussian section Krupp's big gun attracts a great deal of attention. It is a rifled breech-loader, of cast steel, weighing 50 tons; the carriage, which also is entirely of steel, weighs upwards of 15 tons. The diameter of the bore is 14 inches, and the number of grooves of the rifling is 40. A special railway truck was constructed for the transport of this immense piece of ordnance from Essen.

M. Thomas, of Berlin, exhibits some excellent cloth shearing machines with spiral cutters.

In the Austrian department a double carding engine is exhibited by M. Girardon, who places two carding cylinders one above the other instead of side by side, and in this manner effects a considerable economy of floor space.

The Italian section, which until quite lately was unarranged, is now in order, and the splendid collection of ores, in class 40, shows the immense mineral resources of this country. Westerman and Co., of Genoa, show a small pair of horizontal screw engines. Ansaldo and Co., of Sampierdarena, exhibit a trunk piston, connecting-rods, one finished and the other a rough forging, for a marine engine of 660 horse power. There are a good many silk winding machines, but these do not present any novelty in design. A goods waggon and several parts of engines, such as axles, springs, etc., of excellent workmanship, are exhibited by the Roman Railway Company.

The large three-cylinder marine engine, of 960 horse power, made in the workshops of the French imperial navy at Indret, are at work every day. Messrs. Schneider and Co., of Creusot, are well represented in their annexe near the Porte de l'Université. They exhibit three locomotives, two marine engines, a horizontal colliery winding-engine, machine tools, specimens of iron-coal, drawings of engineering works that have been constructed by the firm, plans of workmen's cottages in the commune of Creusot, etc.

This immense establishment, including mines, collieries, &c., occupies an area of nearly 300 acres, of which 47½ acres are covered with buildings. The number of workmen employed on their works is 9,960, with a total engine power of 9,750 horses.

The first locomotive is an express engine, constructed for the Great Eastern Railway (England), from drawings furnished by Mr. R. Sinclair. The next is a goods engine, for the Creusot Railway. And lastly, a small engine for a mineral line of 3ft. 4in. gauge, and weighing about six tons. Since 1838 the Creusot iron works have constructed 1,100 locomotives. The first marine engine is of 950 nominal horse power, for the iron-clad *L'Océan*. It is of the type now adopted by the imperial navy, with three cylinders 84in. in diameter with 4ft. 4in. stroke. The actual power is 3,800 horse, making 55 revolutions per minute. The steam is admitted at high pressure in the middle cylinder, and afterwards allowed to expand in the two others, on the Woolf principle. The slide-valves are moved by an independent crank shaft, situated above the main shaft, so as to avoid the necessity of eccentrics and give more bearing surface. Another marine engine is of 265 nominal horse-power, forming one-half the engine power of the coastguard iron-clad ram, the *Cerbère*, of the imperial navy. The two cylinders are 48in. in diameter, with 2ft. 4in. stroke.

In the Wurtemberg annexe, Messrs. Decker, Brothers, and Co. exhibit Henry Völter's patent machinery for

the manufacture of wood pulp for paper-making. This machinery is driven by three portable engines, of the united power of 50 horses. It consists principally of the "debrier," or grindstone, by which the wood is reduced into fibre, whilst water is continually running over it. The wood is held firmly, and pressed against the stone by a self-acting mechanism, and ground into a mass of fibre. It then passes through a coarse sorting apparatus, in which the splinters of wood are removed. This apparatus separates at the same time the coarse part of the fibre, and conducts it to the refiner, and it also serves for the mixing of the coarser pulp. The refiner consists of a pair of millstones, between which the pulp is ground; it then passes to the sorting apparatus, consisting of a series of cylinders, covered with wire gauze. The different qualities of pulp are sorted according to the degree of fineness, and the different qualities are delivered into tanks. Eighty of these machines have already been constructed, and supplied to various parts of Europe.

The Swiss section contains a good supply of cotton-spinning machinery by Messrs. Rieter and Co., of Winterthur (Zurich), consisting of scutching and lapping machines. The process of double carding is exhibited, that is to say the carding of the cotton in two carding engines only, the "breaker," and the "finisher," with the intermediate process of doubling.

The "breaker" carding-engine is provided with six workers and cleaners; the cotton is taken in the usual manner, by means of a comb, or toothed steel plate, which is made to vibrate in front of the doffer, removing the cotton in a light fleece, the full width of the doffer; the fleece is contracted and drawn through a tube by means of a pair of rollers, and the slivers thus formed are delivered and coiled in a cylindrical tin can, revolving slowly on its own axis.

Twenty-four cans, containing the slivers thus formed, are arranged at the back of the lap doubling machine. The slivers are passed through two pair of callender rolls, and the laps thus formed are wound upon a light wooden bobbin placed in the channel between a pair of fluted rollers; each sliver is provided with a stopping motion, so that if any break, the machine is stopped, and in this manner waste and spoiled work is prevented. Four of the laps thus formed are placed end to end on the finisher card, which is mounted with twenty-four self-stripping flats, on Wellmann's system. The fleece is removed from the doffer in the usual manner, and formed into a sliver, which is coiled in a can revolving on its axis. The drawing frame consists of a series of rollers, through which eight slivers are drawn into one, and deposited in a coiling can. The slubbing frame, in which the sliver is twisted for the first time, is of forty spindles, with the usual bobbin and fly action. The intermediate frame is of 72 spindles, and the roving frame of eighty spindles, with the usual three pairs of drawing rollers each. The rovings from this last are spun into yarn on a self-acting mule.

Messrs. Wegmann and Co., of Baden (Switzerland), exhibit five silk throwing machines of excellent workmanship and arrangement.

M. Honegger, of Ruti (Zurich), some well-made looms for silk weaving.

An important and simple machine is exhibited by M. S. Golay, of Geneva, for dressing and preparing mill stones. The cutting tool consists of a black diamond, held in a notch between two circular steel plates, about three-quarters of an inch in diameter, screwed up tight together, on a small steel mandril, making about 2,000 revolutions per minute. An upright standard is fixed in the centre of the stone, with a long horizontal jib, on which the carriage holding the cutter is made to traverse by means of a screw and hand wheel. In dressing a stone by means of this machine a great economy of time is effected, as compared with hand-dressing, and the work is done with greater accuracy. The diamond, costing four to five shillings, is stated to last about a year.

The United States Sanitary Commission, or rather Dr. Thomas W. Evans, in a small building near the Porte de l'Université, shows an interesting collection of articles for the relief of the sick and wounded, and which rendered great service during the late civil war. Besides several ambulances, in one of which about three thousand soldiers were transported during the war, a model of a railway ambulance, or "hospital car," is shown. This model is a fac-simile of the hospital cars employed by the United States Sanitary Commission on the railway between Washington and New York, as well as on several other military railways in other parts of the States. In this model everything is shown. Couches, of which there are 30; dispensary wine closet; water closet; system of ventilating and heating, &c., as was employed in the construction and equipment of these cars; and externally it represents perfectly the construction of an American passenger car. It is provided with a patent safety break, and a set of self-acting ventilators. The couches are hung from pins in the uprights, by means of four strong rings of vulcanised india-rubber, and in this manner an easy movement is secured with an almost entire absence of concussion, even over the roughest roads. Besides ambulances, several medicowaggons, field dispensaries, models of hospitals, hospital tents, hospital furniture, and surgical instruments, are shown.

Fine Arts.

ARUNDEL SOCIETY.—Mr. Layard M.P., in the absence of Lord Elcho, took the chair at the last annual meeting of this society. In opening the proceedings he dwelt on the favourable aspect of the report. The number of members under the recent reconstruction is likely, in the course of the year, to be doubled, and the annual receipts have now reached upwards of £5,000. This growth in resources has enabled the society to extend the sphere of its operations. In the course of the present year two series of publications will be issued, in place of one, the first and second class of subscribers respectively. These will include chromo-lithographs from frescoes by Raphael, Ghirlandajo, and Razzi. Mr. Layard has kindly undertaken to write for the society a descriptive notice of the Brancacci Chapel, which will be distributed among the members, with the closing illustration of that rich repository of mural decorations. It is anticipated that this critical notice may settle certain historic questions as to the authorship of the frescoes, which have long been subject of doubt. The balance-sheet of the society shows that the arrangement made with the Department of Science and Art for the sale of photographs has lately been brought into successful operation. Among the most important works now in course of execution are chromo-lithographic reproductions of Van Eyck's celebrated picture, "The Adoration of the Lamb," together with the accessory side panels, or painted doors. Also specimen drawings have been made by Signor Mariannucci of Michael Angelo's "Prophets" and "Sibyls" in the Sistine Chapel. In these and other copies Signor Mariannucci has been directed by the council to transcribe more literally than heretofore the ancient frescoes in their actual state of decay. This instruction was given in consequence of the dissatisfaction expressed by many of the members at the modern aspect imparted to professed fac-similes of ancient works. The project, of which we gave notice some weeks since, to reproduce in chromo-lithography a selection from the sepulchral monuments of the middle ages, is in course of being carried into effect. As examples of the successful combination of architecture, sculpture, and pictorial or other surface enrichment, the sepulchral monuments of Italy are deemed to be unrivalled. Accordingly the council of the Arundel Society have engaged Professor

Snaith, of Stuttgart, to make careful copies in colours or monochrome of two valuable monuments in the church of San Giovanni e Paolo, Venice. A favourable specimen of the Professor's works, together with other interesting drawings recently executed, may be seen in the Society's rooms, Old Bond-street. In the prosecution of these important undertakings the Society will obtain valuable assistance through the accession of Mr. Street to the council.

Manufactures.

STEAM-ENGINES FOR COMMON ROADS.—Great efforts are being made in France to introduce steam trains on common roads, for the transport both of goods and passengers, and a company has been formed to carry out the plan on a large scale. Some experiments have been tried in Paris, Nantes, and elsewhere, and the Universal Exhibition, where there is a large collection of traction and other engines of nearly all nations, has given a fresh impulse to the movement. The object in view in France is different to that in England, the loads to be moved are generally lighter, and there is a want of more passenger conveyance at low rates; the engines required are therefore less powerful but faster. The difficulty to be surmounted is the provision of a reserve force for hills and bad pieces of road; several attempts have been made to meet this, and one engine now at the Exhibition, the invention of M. Lermanjat, is said to have solved the problem. When it is desired to increase the power of the engine the two ordinary driving-wheels are thrown out of action and replaced by others, which are so arranged that the substitution can be made in less than a minute; in fact, the speed is reduced from seven or eight to about two miles per hour, while the rate of working of the parts of the machine itself remains the same. The engine now at the Exhibition has been seen more than once on the boulevards around the Champs de Mars, drawing a small omnibus in its train, and although it has only the nominal force of three horses it seems to do its work effectively, it certainly manoeuvres with great ease, and we have seen it mount and descend the Pont d'Alma with great apparent ease. It is reported of it that its first trial took place at Auxerre, where it drew a low-wheeled truck, such as are employed in the streets of Paris, carrying about $1\frac{1}{2}$ ton of goods and 27 persons, making in the whole a load of three tons, going up a long road with a rise of 8 in 100; the average speed, going and returning, was five miles an hour. It is said also to have performed the journey between Auxerre and Avallon, the distance there and back being nearly seventy miles, drawing a very heavy diligence containing fifteen persons; the road presents inclines, varying from 3 to 5 in the 100, and the average speed effected was nearly seven miles an hour. The expenditure for the journey is given at 21 francs (16s. 10s.). The engine has made several excursions around the Champ de Mars, drawing an omnibus carrying eighteen or twenty persons with comparative ease, and it is reported that it has performed about a hundred miles without the slightest disarrangement.

Commerce.

THE WOOL TRADE.—The Paris correspondent of the *Times* says:—"Some statements lately prepared with regard to the results of colonial and foreign sheep farming show that, while the production of wool in Australia had increased from 55 million pounds in 1869 to 114½ millions in 1866, or 108 per cent., that of the River Plate—where the same kind of wool is grown, but which is practically unused in England—increased from 42 millions to 155 millions, or 269 per cent. English woollen manufacturers at present depend

almost exclusively for their supply of fine wool upon the growth of Australia and the Cape, while Continental manufacturers use all three kinds, according to the current value of each. If English consumers, it is remarked by Messrs. J. L. Bowes and Brothers, of Liverpool, would do the same, greater evenness of price would result, without acting prejudicially to the interest of colonial growers. It may be urged that English consumers do not like to use River Plate wool on account of the 'burr,' but it is ridiculous to let a slight mechanical difficulty prevent the use of a wool which, in a few years, will be more abundant than that of any other country. It is mentioned as a well-known fact that Belgian spinners frequently buy burry Buenos Ayres wool in England, take it to Belgium, pick out the burr with a machine invented and often made in England, and, having spun the wool into yarn, return it into England and Scotland for sale and consumption."

Colonies.

HARVEST IN AUSTRALIA.—The returns as to the wheat harvest show that the total crop was about 8,500,000 bushels, which gives a surplus for export of 104,000 tons. In Victoria, too, the yield has been very abundant. Under these circumstances the question of an European market for Australian corn is becoming one of momentous importance to the colonial farmers. The glutted state of the wheat market, together with the effects of the drought on sheep farming, and the closing of the Burra mines have given rise to much discussion on the question of new industries.

Publications Issued.

OFFICIAL ENGLISH VERSION OF THE CATALOGUE OF THE PARIS EXHIBITION (J. M. Johnson and Sons).—A second edition of the English general catalogue has been issued. It is greatly improved and enlarged, but without any increase of price. The new edition contains 1,008 pages, exclusive of advertisements; it is well printed, and exhibits in all respects great care in its production. This new issue is prefaced by a map, printed in colours, and showing not only the place of each country within the Exhibition building, but the position and object of the numerous structures in the park. There is also, in addition to a full general table of contents, a tabular index, specially arranged in such a way that the visitor may either examine the Exhibition class by class or country by country; this is effected, in two pages, by giving in one column the names of all the exhibiting countries, and in 94 other columns the number of the page of each country in each class. It may be added that while the editor of the French edition has only divided the exhibits of each country by groups, Mr. Yapp, the compiler of the English translation, has adhered strictly to the classification, giving the contributions of each country under each class.

Notes.

AERONAUTICAL EXPERIMENTS IN FRANCE.—The first ascent with Nadar's great balloon, the "Géant," was made recently from the esplanade of the Invalides, in Paris. Besides the captain, assistant-captain, and two men, there were in the car M.M. Sourel and Simonin, members of the Meteorological Society of France, and M. W. de Fonville, scientific editor of *La Liberté*. There was some difficulty in getting the great machine to rise, and one person was compelled to descend before the buoyancy was sufficient, but at last the great balloon rose majestically and was soon lost in the clouds. The trip was merely experimental, and M. Simonin records the

few facts observed. The balloon entered the clouds at 660 metres above the earth, and in five minutes after, having ascended 350 metres more, the aeronauts were in full sunlight. The total altitude attained was 1,030 metres; the mercurial barometer marked 674 millimètres, the thermometer 16° centigrade, the hair hygrometer 88½. At the surface of the earth before starting the pressure of the air had been 760 millimètres, the temperature 18°, and the humidity 82. The trip only lasted one hour, and the balloon descended at Chilly, four leagues from Paris, without any further accident than the breaking of a thermometer, the uprooting of an apple-tree, and the knocking off the coping-stones of a wall. The direction was due south, and the force of the wind 18 kilometres, or more than eleven miles an hour. Besides the instruments in the charge of the aeronauts themselves, there were others in the car which were sealed; these were specially contrived by M. Regnault to check the records of the former, and were not to be opened until returned to the College of France. Another ascent is to be made with the same balloon in a few days. On the same day M. Flammarion made a third ascent in the smaller balloon of the Association.

PROPOSED MEMORIAL STATUS FOR THE ISTHMUS OF SUZ.—M. Faustin Glavany, Secretary in the Turkish diplomatic service, and deputed by the Sultan to represent his Government at the Archaeological Congress of Antwerp, has just published a project for a commemorative monument to be erected at the entrance of the canal of the Isthmus of Suez. This monument, which the author proposes to call the Temple of Peace, is to be in the form of a pyramid, as characteristic of Egyptian architecture. On the apex of the pyramid is to be a statue of Peace, bearing in one hand a flambeau, and in the other an olive branch, and on the four sides of the pyramid, and its base, inscriptions in Coptic, Hebrew, Greek, Arab, Latin, French, Assyrian cuneiform character, and Turkish, with sixteen escutcheons, bearing the names of maritime nations or their sovereigns.

Correspondence.

RATING OF INSTITUTIONS.—SIR,—You will perhaps recollect that some months ago a movement was set on foot by the Council of this Institute to obtain exemption from the assessment of Institutions like ours to the Inhabited House Duty, except for those portions actually occupied as dwellings. I have now the pleasure of informing you that the Lords of the Treasury have, on the recommendation of the Board of Inland Revenue, issued an authority for the limitation of the assessment of public buildings devoted to the culture of science, literature, and art, to such portion of the building beneficially occupied as a dwelling, when such portion is of the annual value of £20 or more. Would you kindly notice this in the *Journal* of the present week for the benefit of the managers of other Institutions.—I am, &c., EDWIN SMITH, Secretary.

Birmingham and Midland Institute, 2nd July, 1867.

MEETINGS FOR THE ENSUING WEEK.

Tues ... Ethnological, 8. 1. Mr. J. Thomson, "On the Ethnology of Comodia, with some account of the Jacoons of Johore." 2. Mr. H. C. Crewick, "On the Syllabic Characters in use among the Key Negroes." 3. Mr. G. M. Sprout, "On the Probability of a Stone Age."

Wed ... Royal Literary Fund, 3.

Patents.

Journal of the Society of Arts.

FRIDAY, JULY 12, 1867.

Announcements by the Council.

SOCIETY'S VISIT TO THE PARIS EXHIBITION.

The Council have directed the Secretary to make arrangements for a visit of the members of the Society to the Paris Exhibition. The period fixed for the visit has been extended from Monday, the 29th of July, to Friday, the 16th of August, in order to include the Napoleon fêtes. A reception-room has been provided for the use of the members during their stay, where their correspondence may be addressed, and where they will have the convenience of writing letters, making appointments with their friends, and where notices of all arrangements for visits to various places will be suspended. Lists of hotels and apartments will also be provided there for consultation.

A programme is in the course of preparation. Members contemplating visiting Paris at this time are requested to send in their names to the Secretary, in order that cards of membership and programmes may be furnished to them.

ARTIZANS' VISITS TO PARIS.

Her Majesty's Government have granted to the Society of Arts, in aid of the fund now being raised by the Society for assisting workmen, specially selected from various trades, to visit and report on the Paris Exhibition, the sum of £500, conditional on the Society raising a like amount by public subscription.

The following is the list of subscriptions up to the present date:—

H.R.H. THE PRINCE OF WALES, President ..	£31	10	0
HER MAJESTY'S GOVERNMENT (conditional) ..	500	0	0
Society of Arts	105	0	0
Earl Granville, K.G.	5	0	0
Lord de L'Isle	10	0	0
Thomas Twining	2	2	0
Sir J. P. Boileau, Bart.	5	0	0
George Godwin, F.R.S.	1	1	0
Deputy-Chancellor Sir W. Page Wood, F.R.S. ..	10	0	0
V. H. Bodkin (Assistant-Judge)	3	3	0
Sir Rowland Hill, K.C.B.	3	3	0
Benjamin Shaw	2	2	0

Subscriptions may be forwarded to the Financial Officer, at the Society's House.

The Council are now prepared to receive the names of any workmen recommended by their respective trades as fit and proper persons to undertake this important duty on behalf of their fellow workmen.

Proceedings of the Society.

FOOD COMMITTEE.

A meeting of the Sub-Committee on Fish took place on Tuesday, 28th May. Present: Mr. Benjamin Shaw in the chair; Mr. Ware and Professor J. Wilson.

Mr. JOHN POWELL, fish dealer, of Earl-street, Seven-dials, attended before the Sub-Committee to give information relative to the distribution of fish among the poorer classes in London, &c.

Mr. POWELL stated that he was in the habit of regularly attending the sales in Billingsgate-market, and he handed in to the Committee a copy of the return of the quantity of each kind of fish which was brought into Billingsgate-market for sale on that morning, which it appeared was issued daily on the opening of the market, as a guide to the dealers, and could be obtained by them on application to the market officials. Mr. Powell proceeded to give the following evidence in reply to interrogatories put by the Committee:—

He buys his fish in the usual way, direct from the salesmen generally, but sometimes of the fishermen—some kinds. There is a great deal of fish comes into the market that ought not to be sold, but nevertheless is sold, and distributed about London, in the streets and in shops and stalls—fish which may have been a long time on the passage in bad weather. The vessels lose their ice and the fish is spoilt. Such fish is bought by the lower class of traders and hawkers. There are two inspectors, for the purpose of preventing such fish from being sold, but they are seldom to be seen; sometimes they are not there for hours together. They are supposed to be there, but very often they are not to be seen. I have sometimes seen them condemn fish that was eatable, and at others they have passed that which was bad. All, or nearly all, the fish passes through the hands of the salesmen. It is usually sold by auction, all in a hurry, and the highest bidder for each lot of fish is the purchaser. I buy direct from the salesman, not from a middle man. The sales are for cash, but if you are known on the market you need not always pay cash. I sell direct to the consumers the fish which I buy in the market, but I sometimes send fish to dealers at Reading and Portsmouth. I sell my fish now in a shop; previously to that I got my living by selling in the streets. The quality of that generally sold from the barrows varies—some is good and some bad. That fish is generally bought direct from the market, or from persons like myself. If fish is scarce the barrowmen get it from the “cut-away” shops—these are little shops, but a great deal of business is done in them. I think there is quite as much bad fish in the large shops as in the small ones, because the large shops have ice-wells, where they keep fish for so long a time that at last it becomes bad. The small shops cannot have ice-wells.

Have you ever heard, and are you aware of the fact that a good deal of fish is sometimes destroyed in Billingsgate-market to keep up the price?—A good deal is packed away, day after day, rather than sell it cheaper. Sometimes I have seen fish condemned which was good enough for anyone to eat. The fish is sent to the market on commission. One salesman makes a good price of things, and another will put them by till the next day, because he will not sell at a lower price than others. The next day they bring it out again, and if not sold then it is put away again, or, if kept too long, is sometimes condemned. A very large quantity of fish is distributed in London by hawking it with barrows. As a general rule they do not sell bad or unwholesome fish. They get it as good as the fishmongers; it all comes from the same market. Of course they buy only the cheaper kinds of fish. As regards the prices of fish sold from the barrows, and the same kinds of fish sold in the fishmongers' shops there is a great deal of difference. The fish principally sold from the barrows consists of plaice, and mackerel, and soles when they are reasonable.

What would be the difference in price between fish sold from the barrow and that sold in the larger shops?—They could get from me for fourpence as much as they would have to pay a shilling for at the larger shops, and the quality is the same, as they would be the same kind of fish, bought in the same market; the one would be just as good as the other, and out of the same vessel.

Are the best fish picked out and the refuse sold to hawkers?—No; there is no picking out at all at the market. The fish hawker buys his direct from the salesman.

Are there not a number of middle-men, who buy in large quantities and sell it again to the small dealers?—There are plenty such, but it is only the poor little shops, who may not require more than a dozen plaice or a dozen pair of soles, who buy of them. The fish carried about for sale in the country is purchased by middle-men, who send it into the country by the railways. The poor buy fish largely as an article of food in London, and they would buy more if they could get it. The supply is not generally sufficient for the demand. I could myself profitably dispose of a larger quantity of fish than I can get—three times the quantity, at least. There is a great desire on the part of the poor to eat fish if they could get it. Sometimes for 4d. or 6d., enough for a family of five or six people, and generally such fish as the poorer classes are of good quality, very good, indeed. It is only in very hot weather that there is any bad fish about. It is, however, does not particularly affect the fish sold from barrows, it is sold so quickly. A man generally sells a barrow-load out in about two hours in the morning between ten and twelve o'clock. The fish sold from barrows generally keep good longer than the round ones. Haddocks and whittings have the insides removed when they are packed for the market, and then they keep as long as plaice and other fish.

Have you any idea at what price per lb. you sell fish to the poorer classes when there is a pretty good supply?—Last week I sold good plaice at the rate of a halfpenny per lb., and soles at 3d. per lb.

Is there a large trade in fish in country towns and barrows?—Yes; in all the large towns there is a great deal of fish sold from barrows. In all the towns where they have barrows.

Is not a halfpenny per lb. for plaice and 3d. per lb. for soles an exceptionally low price?—No; at the best of times I do not get more than at the rate of 1½d. or 2d. per lb. for plaice would be considered an extraordinary price. I am obliged to have a large quantity of fish in the week, to serve the Jews living in my neighbourhood, and they will buy only the best quality. I am obliged to have the best plaice and soles that I can get, and I never get more than at the rate of 2d. per lb. for plaice. It is eaten by the Jews on particular days as a relish, and not as ordinary food. At this time of the year there is a great demand for good plaice.

At what price have you sold salmon this year?—At 16d. per lb. I have not much demand for salmon, because of its high price. If I could get salmon which could sell at 1s. or 14d. per lb., I should buy it at a higher price than that I should not get customers for it. The soles which I mentioned as having been sold at 2d. per lb. were irrespective of size. The large ones were charged at a higher rate than the small ones. I could not get a large quantity of salmon at 1s. or 1s. 2d. per lb., but it is not often I can buy it so as to be able to sell it at such a price; the Jew shopkeepers would buy it. Fish sold from barrows, as I have said before, is sold very quickly. I should say there would be none left over the night. At this time of year loads of mackerel are brought into the market late in the afternoon—sometimes about 5 o'clock in the evening. Loads come in from Penzance and they are generally distributed over London and all the same evening.

Is it your opinion that it would be beneficial to have a fish market at the West-end of London?—I do think it would be a great benefit.

The large fishmongers think it would be a great disadvantage, as it would divide the market, and invade their being buyers at each market?—That is very good on their side.

What do you consider would be the advantage to you personally?—There would not be so many people going

one market; and you would know better what you are buying.

Do you think a second market would tend to lower the price of fish generally to the public?—Yes.

Why so?—Because it would compel them to sell the fish, and not keep it hanging on hand all day, or storing it away till the next day.

It would relieve the trade of Billingsgate to some extent, would it not?—There would be only three buyers instead of six for every lot of fish offered.

The great dealers would be obliged to have representatives at each market, and the prices would be telegraphed between the two?—They would be obliged to go to both markets, and that would be a trouble to them.

How is the great bulk of the fish brought into Billingsgate?—By the vessels, and by train. The fish brought by the vessels is generally in the best condition at market, better than that brought by the railways. The fish, when caught, are laid on the cool gravel which the boat has for ballast, and they are not injured, as is the case—particularly with mackerel, which is a very tender fish—by being packed closely together in pads. A pad of mackerel is very soon injured to the extent of 5s. Sometimes out of a pud of 60 mackerel as many as 30 are broken. There are no steamers employed in this service, except those of Hewitt and Co., who have three, I believe; the others are sailing boats. The herrings are mostly brought by train on the Great Northern and Great Eastern Railways, from Yarmouth and Grimsby. They are not of a more perishable nature than mackerel. Very large quantities of fresh herrings are, in the season, brought from Norway. They are packed in boxes, with plenty of ice, and they generally arrive in good condition, and perfectly fresh.

Is there much loss from fish becoming bad in hot weather?—I do not lose much myself from that. At times there are losses of that kind, but I think not often, as the people will sell it cheap rather than have it spoilt. The dealers know what their ordinary consumption is, and they regulate their stock accordingly; but when fish is cheap they buy larger quantities. They sell cheaper, rather than let the fish spoil by keeping. The high-price fishmongers keep the fish in their ice-wells as long as they can. I have sometimes seen fish which has been in ice perhaps for a week, and I should think it would not be very good then.—In reply to further inquiries, the witness stated that a very large trade is done in London in fish for frying, and inferior quality was often bought for that purpose. Broken fish were had by all dealers alike, and they are not sorted out and reserved for the hawkers especially; the large dealers get them as well as the small ones. The market is open to all who choose to buy, and any member of the Committee could go to the market and buy, if he did not object to the pushing and hustling about. The small dealers have an equal chance of buying with the large fishmongers if they are willing to give the price. A large supply of fish daily by the railways would no doubt soon have the effect of cheapening the price of fish in London. He had no doubt treble the present supplies would readily find purchasers. The price of fish had of late years increased fully tenfold. The wholesale prices were very greatly increased for all descriptions of fish—certainly more than double within the last ten years, and the number of buyers seemed to increase in proportion as the supply of fish increased. No matter how much fish was brought into the market, it would all be sold if reasonable prices were taken. The larger quality of soles were packed in trunks, and the smaller in pads; the former fetched the highest prices. Those in the trunks would weigh from three-quarters to two lbs. each. Fish was sent every morning from the market into the country to towns all round London. It was bought and sent off by agents for the purpose, and the persons to whom it was conveyed met the train on its arrival, and took their baskets of

fish. Very large quantities are disposed of every day in that way, which helped to reduce the supply for London itself. Large quantities are sent daily to Portsmouth and Brighton, as well as to other towns. All the fish caught at Brighton is bought wholesale on the beach, by the agents of London dealers, and paid for on the spot; and the fishermen prefer disposing of their fish in that way to sending it to London themselves and waiting for the return of the money. Fish was sent from London every morning as far as to Norwich, although Yarmouth is only eighteen miles distant. The fish owners of that place will not serve the Norwich dealers with one kind of fish without they take other kinds as well, and therefore they send the whole of their fish to London, and the fishmongers in the country have their supply from Billingsgate daily.

Proceedings of Institutions.

CARLISLE MECHANICS' INSTITUTE.—In the report on the close of the forty-third year, the committee, while regretting that they have no great progress to relate, are glad to record that no serious retrogression has taken place. The library now contains between five and six thousand volumes, and during the past year 23 new volumes have been added. Respecting the issue, there is a decrease of 1,710 as compared with last year, when the number issued was 8,698, against 6,988 during this. During the year now closed, two classes were commenced, at the usual time, one for Latin and French, by Mr. Morrison, and the other for mathematics, book-keeping, and other English subjects, by Mr. Rotherham. By a melancholy accident the committee were deprived of the services of the former teacher at the beginning of 1867, and it was thought inadvisable to appoint a successor for the remainder of the session. Three lectures have been given during the year, two by the president, and one by Mr. M. D. Conway on America. The number of full members and annual subscribers is 304, and of reading members 123, making a total of 427. The financial statement shows that the receipts have been £174 5s. 11d., and that there is a balance in hand of £10 5s. 10d.

CHIPPENHAM LITERARY AND SCIENTIFIC INSTITUTION.—The report for last year congratulates the members on the continued success and usefulness of the Institution; the number of members at present is 63, viz., 21 at an annual subscription of £1, and 42 at 10s. The Institution has been favoured with lectures from R. N. Fowler, Esq., on "Mahomet and his Religion;" T. W. Saunders, Esq., Recorder of Bath, on "Criminal Jurisprudence in England;" and the Rev. Canon Jackson, on "Notices of Ancient Chippenham." The library, which has been increased during the past year by the addition of 40 volumes, includes many standard works, and now numbers nearly 800 volumes. The finance account shows that the receipts amounted to £59 12s. 4d., and that there is a balance in the hands of the treasurer of £7 6s. 2d.

EXAMINATION PAPERS, 1867.

The following are the Examination papers set in the various subjects at the Final Examination held in April last:—

ARITHMETIC.

THREE HOURS ALLOWED.

1. A man spends £42 every 28 days, and lays by £50 a year. What is his yearly income?
2. A bankrupt owes £5,920, and his effects realise £3,700; how much can he pay per pound; and how much does he owe to a creditor who receives £401 3s. 11½d.
3. If an engine of 12-horse power pump up 3,200 gallons of water in an hour and a-half from a pit 150 fathoms

deep, how long would the same engine take to raise 2,000 gallons from the mean depth of 100 fathoms?

4. Find by Practice the value of 578½ ounces of gold at the rate of £8 17s. 9d. per oz.

5. Required the amount of 91 cwt. 3 qrs. 13 lbs. of hops at £9 13s. 7d. per cwt.

6. The knot, or nautical mile, is $\frac{1}{60}$ of a degree of latitude, which is equal to 69½ statute miles. By what fraction of a statute mile does the knot exceed that mile?

7. Out of 11 guineas $\frac{2}{3}$ are paid to A and $\frac{1}{3}$ to B, after this $\frac{2}{3}$ of the remainder are paid to A and the rest to B. What sums did each receive?

8. A cistern can be filled by one pipe in 20 minutes, by another in 30 minutes; a third pipe can empty it in 12 minutes. Suppose the cistern to be half full, and the three pipes set open at once, in what time will it be full?

9. If $\frac{3}{4}$ of $\frac{4}{5}$ of a yard cost $\frac{7}{10}$ of a crown, how many francs ought I to pay for 3 yards, the franc being reckoned at 10d.?

10. A ship, with a crew of 48 men, and provisions for 40 days, is becalmed; the captain reduces the daily allowance from 2 lbs. to 1½ lb., and sends away, by a passing steamer, a portion of his men, by which he was enabled to hold out for 45 days. How many men were sent away?

11. How many men will be required to dig a trench 64½ yards long, 10½ feet wide, and 2½ feet deep, in 2½ days of 9½ hours each, when it took 9 men 2½ days of 10 hours each to dig a trench 81 yards long, 12½ feet wide, and 1½ feet deep?

12. What number of works, each consisting of 2 vols., and each volume 2·47 inches thick, would fill 4 shelves, when 19 works, each 3 vols., and each volume 1·3 inch thick, fill 10 such shelves?

13. What is the difference, in the present currency, between £2 7s. 9½d. and £2 7 florins, 9 cents., 3 mills?

14. At what rate per cent. per annum, simple interest, will £350 amount to £399 in 4 years?

15. In what time will £2,750 gain £412 10s. at 5 per cent. per annum?

16. What is the difference between the banker's discount and the true discount of £517 10s. for 7 months at 6 per cent. per annum?

17. If the 8 per cent. Consols be at 90, what should be the price of a £50 railway share paying 4 per cent., that the two investments may be equally advantageous?

18. Bought cinnamon at 7s. per pound, and sold half of it at 6d. an ounce. At what price per ounce may I sell the other half, that the gain on the whole may be 10 per cent.?

19. I have paid to day £2,180, being repayment, with interest, of two loans, both contracted at the same time, viz., £1,183, borrowed at 4 per cent. per annum, and £994 at 4½ per cent. per annum. How long is it since the sums were borrowed?

20. I bought a horse for 25 guineas cash, and sold him the same day for 30 guineas, with such allowance of credit as made my immediate gain 17 $\frac{1}{2}$ per cent. What term of credit did I allow?

BOOK-KEEPING BY DOUBLE ENTRY.

THREE HOURS ALLOWED.

1. Journalize and post, in proper technical form and language, the following imaginary transactions, and make out from the ledger a trial balance, a profit and loss account, and a balance-sheet.

On 1st January, 1867, John Ward and W. Campbell have assets and liabilities as follows, viz. :—

Assets.	£	s.	d.
Business premises and plant, valued at	1,500	0	0
Sherry	3,525	0	0
Brandy	500	0	0
Due by J. Smith	100	0	0

Bills receivable	200	0	0
Cash	1,115	0	0

LIABILITIES.

Bills payable	750	0	0
Due to P. Robb	200	0	0
John Ward's capital is	3,300	0	0
W. Campbell's „	2,075	0	0

They take J. Smart into partnership on the 1st January 1867. J. Smart's capital amounts to £2,500 in cash.

N.B.—The capital and drawings of the partners are subject to interest at 5 per cent. per annum, and the balance of profit and loss is divisible thus—to John Ward one-half; to W. Campbell and J. Smart one-quarter each.

1867.		£	s.	d.
Jan. 1.	Advanced for petty cash	20	0	0
	Sold J. Smith, brandy	12	0	0
„ 2.	Paid cash for our acceptance of J. Duncan's draft, due this day ..	200	0	0
Jan. 5.	Discounted J. Green's acceptance for £200, and received £198 in cash and allowed for discount £2 Bought of J. Smith, sherry	200	0	0
	Accepted J. Smith's draft, at two months' date	600	0	0
„ 8.	Invoice of brandy bought of S. Nokes	1,085	0	0
„ 9.	Received consignment of claret from T. Sandford, to be sold by us on his account, at 2 per cent. commission on proceeds, invoiced at	800	0	0
	Paid cash for carriage of above consignment	2	0	0
„ 10.	Advanced cash to T. Sandford ... Paid cash for additional business premises	100	0	0
„ 12.	Cash paid S. Nokes for brandy ... Discount allowed by S. Nokes ... Sold W. Brown, brandy	1,015	0	0
	Sold W. Brown, sherry	500	0	0
	Received W. Brown's acceptance, at 21 days	550	0	0
„ 15.	Cash drawn out by W. Campbell	100	0	0
„ 20.	Consigned to R. Green, to be sold by him on our account and risk, sherry, invoiced at	200	0	0
„ 27.	Lent cash to J. Smith	100	0	0
„ 29.	Bought sherry of P. Robb ... Paid P. Robb on account, by handing to him W. Brown's acceptance for £550	625	10	0
	Sold brandy for cash	800	0	0
	Sold sherry for cash	850	0	0
„ 31.	Sold for cash part of consignment of claret from T. Sandford ... Paid salaries of clerks	150	0	0
	Trade charges, paid out of petty cash	45	0	0
	Interest on amount drawn out by W. Campbell	0	4	0
	Interest on J. Ward's capital	16	5	0
	„ W. Campbell's capital	8	12	0
	„ J. Smart's capital	10	0	0
	Estimated wear and tear of business premises and plant	10	0	0
	Commission earned on consignment of claret	8	0	0
	Stock of sherry on hand	3,475	0	0
	„ brandy „	960	0	0

2. What is book-keeping by double entry as distinguished from single entry?

3. Describe what is the import respectively of the terms *personal*, *real*, and *nominal*, as applied to accounts.

4. How is the account of profit and loss affected if on

the books, (a) the value of the stock of goods on over-estimated; (b) if a known bad debt is reckoned as one?

On examining the books, it be found that the fol-
lowing, viz., "Accepted John Smith's draft, at two
£100," has been journalized and posted as if it
"Received John Smith's acceptance, at two
£100," what journal entry or entries would be
to correct the error?

ALGEBRA.

THREE HOURS ALLOWED.

Reduce to their simplest forms—

$$\frac{x}{x-y} + \frac{y}{x+y}$$

$$\frac{x}{x-y} - \frac{y}{y+y}$$

$$\frac{\sqrt{a+b}}{\sqrt{a+b}} + \frac{\sqrt{a-b}}{\sqrt{a-b}} - \frac{\sqrt{a+b}}{\sqrt{a+b}} - \frac{\sqrt{a-b}}{\sqrt{a-b}}$$

Solve the equations $x^3 + x^2 - x - 1 = 0$.

$$\begin{cases} x^2 - xy = 70 \\ xy - y^2 = 21 \end{cases}$$

Extract the square roots of the binomial surds.

$$43 - 30\sqrt{2}; \sqrt{20} - \sqrt{15}$$

There are 10 flags; 1 white, 2 red, 3 blue, 4 yellow;
signals are made by employing them all at the same
one over the other. How many signals can be thus
made?

The first and seventh term of a geometrical series
; 30 and 1,920, find the sum of 13 terms of the same.

A requisition for 87,500lbs. of bread was levied upon
certain number of villages in equal portions; subse-
quently two of them fell into the power of the enemy,
the whole amount had to be contributed by the
remaining ones, who, in consequence, each contributed
10lbs. more than under the original terms of the levy.
How many villages were there?

The interest on a certain sum of money is £225, and
discount on the same for the same time £187 10s.
What is the sum?

Find the value of $(x-c)^2(x+2c)$; and hence de-
termine the relation that must subsist between q and r , in
order that the equation $x^3 + qx + r = 0$, may have
three equal roots.

9. Prove that the sum of the series,

$$+n^2 + \left(\frac{n-1}{2}\right)^2 + \left(\frac{n-1}{2} - \frac{n-2}{3}\right)^2 + \text{etc.},$$

equal to the coefficient of x^n in the expansion of
 $(1+x)^n$ and show that this latter is $\frac{1 \cdot 2 \cdot 3 \dots 2n}{(1 \cdot 2 \cdot 3 \dots n)^2}$

10. A race is to come off between two boats, in each of
which three rowers are to be placed, chosen by lot out of
six men, whose relative powers of propulsion are repre-
sented by the numbers 7, 8, 9, 10, 11, 12. Find the
chance that one at least of the two middle men will be
among the winners in the race.

11. If $x^3 + y^3 + z^3 = mxyz$, and
 $x^3 + y^3 + z^3 - 3xyz - y^2z - z^2y - x^2z - zx^2 = 0$, show that there
are eighteen systems of ratios, $x : y : z$, which satisfy
the above equations and obtain their values.

(To be continued.)

FINAL EXAMINATIONS, 1867.

The following additional certificates have been
awarded:—

119—Houston, Alexander, aged 18, Belfast Academy,
teacher—Arith. (1st); Alg. (1st); Geom. (2d).

121—McNeill, Henry, aged 17, Belfast Academy, teacher
—Arith. (1st); Alg. (1st); Geom. (2d).

PARIS EXHIBITION.—AWARD OF PRIZES.

The list of prizes which appeared in the *Journal*
last week was translated from the proof-sheet of the
list compiled by the Imperial Commission, who have
now issued a revised list, which has many important
variations. Even this is not to be wholly relied upon,
and it is undergoing revision. As soon as possible a
complete list will be printed. The following corrections,
especially referring to the list of the grand prizes, may,
however, be made. The number of grand prizes awarded
to the United Kingdom is nine, namely:—

GROUP 1.—Class 4 (Architectural Designs)—Mr.
Waterhouse, of Manchester.

GROUP 5.—Class 43—British India (cotton).

Class 40—Bessemer (production of steel).

GROUP 6.—Class 51—Mr. C. W. Siemens, London
(regenerative gas furnace).

Class 54—Whitworth Company, Manchester (machine
tools).

Class 64—Atlantic Telegraph Company.

Class 66—The Life-boat Society (for organization and
material for saving life).

Messrs. Napier, Glasgow; and Messrs. Penn, Green-
wich.

Messrs. Siemens Brothers were classed by the jury for
a grand prize in Class 64, Telegraph Apparatus, and the
Lords of the Admiralty for a series of models of the
internal arrangements of ships of war, but the former
were *hors concours* on account of one of the members of
the firm being a juror, and the Admiralty declined to
compete for rewards.

Parties of working men continue to arrive from all
parts of Europe to visit and study the Exhibition; 250
Danes reached Paris at the end of last week, under the
guidance of M. Walfhagen, vice-president of the
Danish Commission. A special vessel was chartered to
convey the party to France, and the visitors are lodged
in the Pavillon de Sully, at the cost of a Commission
specially formed to assist workmen visitors; they are to
stay in Paris nearly a fortnight. The next party ex-
pected is from Turin, and will consist of workmen and
manufacturers, sent at the cost of the province of Turin.
Before leaving home, they were received by the Prefect
of Turin, who wished them a pleasant journey, and gave
them some counsel as to studying the Exhibition in such
a manner as to make their visit profitable to the town
and province of Turin. A considerable number of
Belgian workmen are expected in Paris in the month of
August; this visit is the result of the efforts of M.
Dupré, the Belgian Commissioner, acting in concert
with the Commission above referred to. In this case,
and probably, also, in those already cited, the workmen
will be brought over without cost to themselves.

The aquatic competitions commenced on the 7th, and
were to be continued until the 12th instant. Five cutters
have arrived from England, including that of Oxford
University, and one from Canada.

WORKS IN BRONZED CAST-IRON.

The American Department of the Paris Exposition
contains a numerous collection of lamps of various
kinds, clock-cases, and other works, all of them executed
in bronzed iron, which have attracted the attention of
all visitors. They are the productions of Tucker's
Manufacturing Company, established in the City of
Boston, and they are the results of experiments that
have been carried on by Mr. Tucker during the last
seventeen years.

The material employed is American iron of several

varieties compounded together, with a comparatively small admixture of the Scottish Coultness iron. A combination of several important qualities is thus obtained, and a material is produced possessing smoothness in working, softness, and also a sufficient degree of strength. The castings, having been executed in green sand, undergo the customary process of pickling in dilute sulphuric acid, after which they are finished on their salient points either with the lathe or the emery-wheel, as may appear to be most expedient for the polishing; the beautiful granulated velvet-like surface of the mat or field, however, upon which the polished portions of every design appear to rest, is produced by the action of the acid only, and without the application of any kind of tool. The bronzing—the final stage of the manufacture—is accomplished by the means about to be described, imparting to the metal a colour that becomes part of itself.

The iron, covered with a film of vegetable oil, is exposed to heat of a high temperature (the degree of the temperature and the duration of the exposure having been determined by experiment), and thus the desired colour is obtained, through the union of the carbonised oil with the oxydised metal. This, accordingly, is a *permanent* bronzing, since it is actually incorporated with the substance of the metal; and, consequently, the works thus produced are not liable to injury from the action of the atmosphere, from the touch of the hand, from changes of temperature, from excessive damp, or from various other casualties to which they may be exposed. In some degree the bronze surface produced on the cast-iron by this process appears to resemble that of certain steel pens, which have a bronze-like aspect; but there exists no real resemblance between these two classes of productions, since, in the case of the steel pens, a superficial varnish (which may be removed by the application of alcohol) is added to the oxydised metal, and deposited upon it, but not incorporated with it.

The designs for the lamps, clock-cases, and other works exhibited by Mr. Tucker at Paris have been furnished in every instance by Mr. Francis Fracker.

This Tucker bronzing process, which is patented in England and France as well as America, may be applied to the decoration of stoves, iron bedsteads, and many other works in iron, which at present are usually coated with lacquer or varnish.

Specimens of the Tucker collection exhibited at Paris have been secured for the South Kensington Museum.

PRODUCTION AND CONSUMPTION OF EGGS.

A writer in the *Grocer* says:—
